**TITLE: METHOD AND SYSTEM FOR CALCULATING THE SPATIAL-  
TEMPORAL EFFECTS OF CLIMATE AND OTHER ENVIRONMENTAL  
CONDITIONS ON ANIMALS**

25 **BACKGROUND**

The present invention relates to methods for predicting the effects of climate and other environmental conditions on the well-being of animals. Specifically, it relates to a method for accurately calculating the spatial-temporal effects of a variety of environmental conditions on animal individual, population and community dynamics, given the animal's temperature-dependent behaviors, morphology and physiology, by running integrated microclimate and animal models to calculate the discretionary energy and water available to the animal and its activity time.

Animals are affected by the climate and other environmental conditions in which they live. Climate affects animal heat and mass balance and, consequently, body temperature. Spatial and temporal variation in the thermal environment provides a template on which 5 physiological, population and community dynamics are played out. A current challenge in biology is understanding how and when those environmental conditions affect developmental processes and function during the lives of animals. An ability to calculate those effects would enable more accurate prediction and informed decision-making in the management of animal environments. Current trends in global climate shifts, land use and changes to other 10 environmental conditions such as diseases and increases in pesticide use, drive the need for a means to accurately predict their effects to prevent, or at least diminish, their negative impacts on the well-being of animals. The problem is how to model the spatial-temporal effects of climate and other environmental conditions on animals to enable the accurate calculation of those effects.

15 Explicit calculations of how climate affects animal heat and mass balance, and the consequences for body temperature, were first made in the 1960's (Norris, K.S. 1967. *Color adaptation in desert reptiles and its thermal relationships*. In: Symposium on lizard ecology, pp. 162-229. U. of Missouri Press, Columbia, Missouri; Bartlett, P.N. and D.M. Gates, 1967. *The energy budget of a lizard on a tree trunk*. Ecology 48:315-322). Those early models 20 were limited by the lack of models for distributed heat generation internally, distributed evaporative water loss internally, and a first principles model of gut and lung function. Also missing were a first principles model of porous insulation for fur or feathers, an appendage model, and a general microclimate model that could use local macroclimate data to calculate the range of local microenvironments above and below ground.

25 Since then, several developments have occurred to improve our ability to model the effects of environmental conditions on animals. These include the estimation of convection heat transfer properties from the volume of an animal (Mitchell, J. W. 1976. *Heat transfer from spheres and other animal forms*. Biophys. J. 16:561-569), a countercurrent heat exchange model for appendages and modifications based on appendage shapes (Mitchell, J. 30 W. and G.E. Myers, 1968. *An analytical model of the counter-current heat exchange phenomena*. Biophys. J. 8(8):897-911; Wathen, P. *et al.*, 1971. *Theoretical and experimental*

studies of energy exchange from jack rabbit ears and cylindrically shaped appendages. Biophys. J. 11(12):1030-1047; Wathen, P. et al., 1974. *Heat transfer from animal appendage shapes-cylinders, arcs, and cones.* Trans. of the ASME. November. 40:536-540), the ability to understand the effects of convective heat transport (Kowalski, G.J. and J.W. 5 Mitchell, 1976. *Heat transfer from spheres in the naturally turbulent, outdoor environment.* J. Heat Transfer 98(4):649-653), the development of a general purpose microclimate model (Beckman, W.A. et al., 1971. *Thermal model for prediction of a desert iguana's daily and seasonal behavior.* Trans. ASME Paper No. 71-WA/HT-35:1-7; Porter, W.P. et al., 1973. *Behavioral implications of mechanistic ecology: Thermal and behavioral modeling of desert 10 ectotherms and their microenvironment.* Oecologia 13:1-54; Mitchell, J.W. et al. (eds) 1975. *Microclimatic modeling of the desert*, pp. 275-286. Scripta Book Co., Washington, D.C.), the ability to calculate the percent of thermally available habitat (Grant, B.W. and W.P. Porter 1992. *Modeling global macroclimatic constraints on ectotherm energy budgets.* Am. Zool. 32:154-178), the development of porous media models (Kowalski, G. J. 1978. *An analytical 15 and experimental investigation of the heat loss through animal fur.* In: Department of Mechanical Engineering. University of Wisconsin, Madison, Wisconsin.), the extension of the models to radial instead of Cartesian coordinates and the implementation of first principles fluid mechanics in the porous media (Stewart, W.E. et al., 1993. *Prediction of forced ventilation in animal fur under ideal pressure distribution.* Functional Ecology 7:487-492; 20 Budaraju, S. et al., 1994. *Prediction of forced ventilation in animal fur from a measured pressure distribution.* Proc. Roy. Soc. London B 256:41-36; Budaraju, S. et al., 1997. *Mixed convective heat and moisture transfer from a horizontal furry cylinder in transverse flow.* Int. J. Heat and Mass Transfer 40:2273-2281), and a test of an ectotherm and microclimate model to estimate a species' survivorship, growth and reproduction at a continental scale 25 (Adolph, S.C. and W.P. Porter, 1993. *Temperature, activity, and lizard life histories.* Am. Nat. 142:273-295; Adolph, S.C. and W.P. Porter, 1996. *Growth, seasonality, and lizard life histories: Age and size at maturity.* Oikos 77:267-278). However, none of these attempts have accomplished the goal of creating a fully integrated set of models that incorporate all of the conditions needed to accurately predict how animals (both ectotherm and endotherm) 30 will react to changes in their environment.

## SUMMARY

The present invention is directed to overcoming these limitations by providing a system and method to enable users to accurately calculate the effects of climate and other environmental conditions, and the spatial and temporal variation thereof, on the temperature

5 dependent behavior and physiology of animals, and the subsequent effects of those same conditions on population dynamics and community structure.

Accordingly a methodology for accurately predicting the spatial-temporal effects of environmental conditions on animals is presented. Several objects and advantages of the present invention are:

10 a) to provide improved and fully integrated microclimate and animal models which may be used in coordination to accurately predict the effects of climate and other environmental conditions (including artificial environments) on animals, requiring relatively few, easily measured data to estimate food and water requirements, potential for activity time, growth, and reproduction for a wide variety of habitats;

15 b) to provide a methodology that can generate the information necessary to identify potential reserves and/or transplantation sites, and to modify and/or manage existing habitats to optimize the growth, reproduction and survivorship of threatened or endangered species;

20 c) to provide a method that enables the incorporation of the spatial-temporal variation in vegetation and topography in the analysis of the effects of environmental conditions, such as changes in global climate, land use, diseases and toxicants, on animals;

25 d) to provide a means to accurately calculate discretionary energy and water from first principles, thus enabling the calculation of growth and reproduction under any kind of environmental circumstance, and under any kinds of animal characteristics;

30 e) to provide a microclimate model with a solar radiation model incorporated therein, the solar radiation model enabling the input of solar radiation information from the geographic coordinates of the locality, thus eliminating the need for direct measurements at the site, the solar radiation model further allowing for the calculation of the effects of slope on the amount of solar radiation incident on the surface and for the calculation of solar radiation when the sun is positioned below the local horizon;

15

- f) to provide a microclimate model able to calculate the effects of vegetation on the temperature and wind profiles, topography on air temperature profiles over elevation, and the effects of slope on the temperature;
- g) to provide an interactive combination of heat and mass transfer engineering and specific aspects of an animal's morphology, physiology and temperature-dependent behaviors, to calculate an animal's preferred activity time (*i.e.*, the time that minimizes size-specific heat/water loss);
- 10 h) to provide an animal model that incorporates a porous media model for insulation improved by the addition of a solar radiation component enabling the user to calculate the absorbed solar radiation when an animal is in the sunlight;
- i) to provide a porous media model further improved by the addition of an appendage model for birds and other animals to account for energy fluxes at their appendages;
- j) to provide an animal model further improved by the incorporation therein of molar balance models for the lungs and gut to allow for the coupling of food ingested to respiratory gas exchanges and evaporative water loss from the respiratory system;
- k) to provide a means of estimating the food intake of animals in natural circumstances using a gut model based on first principles rather than regression analyses;
- 15 l) to provide an improved means of calculating heat loss from an endotherm by incorporating the effects of solar radiation and relative humidity as factors in the calculation;
- m) to provide an animal model further improved by the incorporation therein of a thermoregulatory model that yields metabolic calculations as a function of temperature and incorporates temperature regulation responses by the animal to maintain a core-skin temperature gradient above a user-specified minimum value;
- 20 n) to provide a means of implementing the models such that a user may run the models with access to large databases of environmental and animal data on a variety of platforms, including a personal computer; and,
- o) to provide a means by which a user is able to specify the conditions set used by the model(s) and/or the results calculated by the model(s), in order to customize the model to the user's particular needs.

25

30

Further objects and advantages of the present invention will become apparent from a consideration of the drawings and ensuing description.

## BRIEF DESCRIPTION OF DRAWINGS

5 In the accompanying drawings:

**FIG. 1**, is a flow diagram of the general method for the present invention that also represents a logic flow that can be implemented in discrete circuits.

**FIG. 2**, is a summary of the general method for the animal model.

10 **FIG. 3a**, is a diagram of a cross-section of an animal with porous insulation and heat fluxes including uniform heat generation per unit volume and uniform heat dissipation by respiration per unit volume.

**FIG. 3b**, is an illustration of the coupled heat and mass transfer equations and how the models may be used to calculate the energetic consequences of climate-disease-toxicant interactions and to assess energetic constraints on community structure.

15 **FIG. 4**, is a representation of the molar balance models of respiratory and digestive systems coupled to each other and to metabolic heat demand to maintain core temperature.

**FIGS 5a to 5d**, present a key to the variables used in the drawings and algorithms.

20 **FIG. 6**, is a graph showing results generated by the present invention, that show the variation in metabolic rate as a function of mass and temperature for the Orange-bellied Parrot.

**FIG. 7**, is a plot of the spatial variation in soil degree days in relation to the range of the Chuckwalla lizard, generated by the present invention to discover the effects of temperature on the lizard's distribution.

25 **FIG. 8**, is a flow diagram depicting the general system of the present invention as implemented in a client-server environment.

**FIG. 9**, is a spatial plot summarizing the discretionary energy of a 60 kg Mountain Lion for the month of July, as a function of slope and aspect of the topography of a portion of its range.

**FIG. 10**, is a depiction of the basic components of the system of the present invention.

## OVERVIEW

The present invention is a method and system for calculating the spatial-temporal effects of a variety of environmental conditions (including macroclimate, topography, vegetation and the like) on animal individual, population and community dynamics, given the animal's temperature-dependent behaviors, morphology and physiology. The method for the present invention comprises using two integrated models, a microclimate and animal model, to translate the environmental and animal conditions into their effects on an animal's energetics and behavior. The system of the present invention sets forth a way in which the methodology may be employed by users via a wide range of computerized platforms.

Referring to **FIG. 1**, an overview of the method for the present invention is presented. The two integrated models of the present invention include a microclimate model **300** and an animal model **500**. The microclimate model **300** translates the environmental conditions into the microclimatic conditions above and below ground that may be experienced by an animal at a specified location. The animal model **500** calculates the effects of the microclimatic conditions on an animal's metabolic and other variables. Those results are then available for further calculations aimed at assessing the ultimate effects of the environmental conditions on an animal's physiological performance, geographic distribution and community dynamics.

The microclimate model **300** of the present invention improves upon a basic model previously disclosed in Porter *et al.* 1973 (ref. above) and by McCullough and Porter (1971. *Computing clear day solar radiation spectra for the terrestrial ecological environment*. Ecology 52(6):1008-1015). The improvements to the microclimate model **300** include the incorporation therein of a solar radiation model. The solar radiation model enables the input of solar radiation information from the geographic coordinates of the animal's locality, eliminating the need for direct measurements at the site. The solar radiation model also allows for the calculation of solar radiation when the sun is positioned below the horizon in addition to when the sun is above. The microclimate model **300** is further improved in being able to calculate the effects of vegetation on the temperature and wind profiles, and the effects of slope on the temperature, as well as enabling a user to select the heights and depths above and below ground at which the microclimates are characterized.

The animal model **500** of the present invention builds upon the fact that in biological systems, mass and energy are interconnected. For example, the amount of mass consumed by

an animal is related to the amount of chemical energy that can be liberated by metabolic processes in the form of heat. Earlier attempts to develop coupled equations of heat and mass balance to quantitatively measure the metabolic variables involved in each were reported in two earlier works (Porter, W.P. and P.A. McClure, 1984. *Climate effects on growth and 5 reproduction potential in *Sigmodon hispidus* and *Peromyscus maniculatus**. In: 'Winter Ecology of Small Mammals.' J. Merritt (ed), at pp. 173-181; W. P. Porter, 1989. *New animal models and experiments for calculating growth potential at different elevations*.

10 Physiological Zoology 62: 286-313). These earlier developments illustrate that relatively few variables can govern processes at multiple levels of biological organization. For example, accurate solutions for the discretionary energy and mass of an animal may be used to calculate the life history variables of growth and reproduction, and solutions for the total annual activity time of an animal may be used to calculate survivorship. The fact that accurate calculations of these few metabolic variables can predict effects on animals, underpins the robustness and broad applicability of the animal model **500** of the present invention.

15 An earlier attempt to couple an animal model to a microclimate model in order to predict the effect of climate and other environmental conditions on animals, was reported in W.P. Porter *et al.* (1994. *Endotherm energetics: from a scalable individual-based model to ecological applications*. Aust. J. Zool., 42:125-162 ). The animal model **500** of the present invention builds upon this earlier attempt and incorporates several improvements that enable the model to more accurately predict the effects of environmental conditions on animals when integrated with the microclimate model **300**, and that enable its application to both 20 endothermic and ectothermic animals.

25 These improvements of the animal model **500** of the present invention, are disclosed herein and include several additions or modifications to some of the components of the previous version, including: (1) the incorporation of a solar radiation component into the porous media insulation model to enable the calculation of absorbed solar radiation when the animal is exposed to light; (2) the inclusion of an appendage model to improve the accuracy of the heat balance analysis by inclusion of the heat exchanges at the appendages of large 30 birds and mammals; (3) the inclusion of a novel thermoregulatory model that yields metabolic calculations as a function of temperature and incorporates temperature regulation responses (behavioral and physiological) by the animal to maintain a minimum core-skin temperature

gradient; (4) the ability to track the time an animal is active/feeding to calculate a total annual activity time; and, (5) the inclusion of molar balance models for the lungs and gut to allow the coupling of food ingested to respiratory gas exchanges and evaporative water loss from the respiratory system.

5 The animal model **500** calculates heat (*i.e.*, energy) and water mass balances for required animal expenditures that are contingent on their selected or maintained core temperature and, from that, further calculates the required wet food intake that is constrained to be no greater than the body mass per day. Activity time calculations depend on light or no light availability and local microclimates that may force heat or water stress and reduce or  
10 limit activity. Together, the subroutines of the model **500** comprise an integrated basic principles model for understanding animal energetics. When coupled with Geographical Information Systems (GIS) based information on climate, topography and vegetation, the integrated microclimate **300** and animal **500** models can be used to generate spatially explicit interpretations of animal energetics and behavior.

15 The method for implementing the present invention provides a means by which a user may run the models of the present invention with access to large environmental conditions and animal databases on a wide variety of computerized platforms, including a personal computer.

20 While the methods disclosed herein may be described and shown with reference to particular steps performed in a particular order, it will be understood that these steps may be combined, sub-divided, or re-ordered to form an equivalent method without departing from the teachings of the present invention. Accordingly, unless specifically indicated herein, the order and grouping of the steps is not a limitation of the present invention.

25 Referring now specifically to the figures, in which identical or similar parts and/or steps are designated by the same reference numerals throughout, detailed descriptions of the method and system of the present invention are given. It should be understood that the following detailed descriptions relate to the best presently known embodiments of the invention. However the descriptions are not intended to limit the invention to those applications. Rather, the present invention is intended to apply to other types of animal  
30 individual, population, and community research, and any other application to which the technology may be beneficially applied. For example, the invention can be applied to other

conservation applications and to the prediction of global and other climate changes on animal distribution, growth and survivorship, in order to develop intervention procedures to ensure their well being. The present invention can, therefore, assume numerous other embodiments, as will become apparent to those skilled in the art, without departing from the appended

5 claims.

## DETAILED DESCRIPTION – METHOD OF CALCULATING EFFECTS

The models of the present invention comprise several algorithms with terms that are defined in the following detailed description. Please refer to **FIGS. 5a to 5d** for a list of terms  
10 and their definitions.

### a. Data Inputs

Referring to **FIG. 1** (a flow diagram of the method for the present invention), two sets of data are distinguished as input to the microclimate **300** and animal **500** models of the present invention. One is a set of environmental conditions data **120** and the other is a set of animal characteristics data **170**.

#### i. Set of environmental conditions data **120**

The environmental conditions data set **120** is a collection of data from an environmental conditions database **100** and from a user-defined set of variables and conditions **150**.

The environmental conditions database **100** is comprised of data relating to climate, topography, soil type and vegetation per locality and time. These data may be available from public sources (such as the National Oceanic and Aeronautics Administration, NOAA) and/or other sources [e.g. soil properties and vegetation type data – may be generated by using programs designed to do so, from data collected at local biogeography labs, or from other sources (e.g. Ramankutty and Foley. 1999. *Estimating historical changes in global land cover: Croplands from 1700 to 1992*. Global Biogeochemical Cycles 13:997-1027) ; certain climate information – from individual climate stations and/or from global climate data sets (such as that of Leemans and Cramer. 1991. *The IIASA database for mean monthly values of temperature, precipitation and cloudiness on a global terrestrial grid*. Laxenburg, Austria, International Institute for Applied Systems Analysis); and, spatial locations data – from the United States Geological Survey (USGS)]. Climate data may include temperature, rainfall,

wind velocity and direction, and solar and infrared (IR) radiation. Vegetation data may include type and abundance of plant cover. Topographic data may include the slope and aspect of the terrain and soil type. Other types of data may also be input to the models if desired by the user and as they become available.

5 The user-defined variables and conditions **150**, input to the environmental conditions data set **120**, may include a set of localities and definition of time intervals over which the models are to be run, the types of vegetation or other food type(s) that comprise an animal species' diet, and the preferred temperature range and average height above ground of the animal.

10 Localities may be defined by latitude and longitude (which, in 0.5 degree increments, define approximately  $30 \times 30 \text{ mi}^2$  areas), by use of the universal transverse Mercator (UTM) grid system to define smaller areas in the range of  $30 \times 30 \text{ m}^2$ , or by other means. Other locality size increments are also possible. By defining the localities set, a user may determine the geographic scale of the microclimate conditions data **400** and of the analysis generally.

15 For example, the analysis of the present invention may span an animal species' home range at the individual level, the distribution of individuals at a particular population's level, or it may span the entire species' distribution worldwide.

20 Time intervals may likewise be defined so that the models (both microclimate **300** and animal **500**) compute outcomes over customizable time intervals. For example, the time intervals may be specified to calculate hourly, daily, monthly, yearly or other time periods according to the user's desired analysis. In one embodiment, the time intervals will be set to analyze conditions during an average day of each month, over each month in a year to analyze animal conditions over an entire year.

## ii. Set of animal characteristics data **170**

25 The animal characteristics data set **170** is a collection of data from an animal characteristics database **190** and from a user-defined set of variables and conditions **150**.

The animal characteristics database **190**, is a compilation of data over many species of animals. The animal characteristics database **190** includes data on a species' morphology, body allometry (*i.e.*, dimensions, weight, geometry and the like), physiology (including core 30 temperature) and other information. Morphological data include those relating to spatial reflectance and include mean length of fibers (*i.e.* fur or feathers), fiber density as a function

of depth, fiber diameter, depth of insulation, and solar reflectivity and transmissivity of fibers.

In addition to the data available from the animal characteristics database **190**, the user may define a set of variables and conditions **150** for the particular species of concern that also make up the animal characteristics data set **170**. User defined variables and conditions **150** 5 may include the average height of the particular animal species specified, the minimum core-skin temperature gradient, the animal's null condition [*i.e.* when it is active (*e.g.* whether it is diurnal, nocturnal, crepuscular), and/or where it is active (*e.g.* whether it is arboreal or fossorial)], the animal's food type and quality (*i.e.* the proportions of carbohydrate:protein:lipids; percent dry matter), percent digestive efficiency, percent water in feces, percent urea in 10 urine, and a multiplier from 1 to 7 above basal metabolic energy requirements to specify food intake to meet current needs, among others. The user may define whether and what pollutants (such as pesticides) are present in the localities, and whether and what other species (*e.g.*, competitors, predators, prey) are present. The user, by inputting particular types and values of the data, may generate model outputs customized to their particular inquiries.

15 **b. Microclimate model 300**

16 The microclimate model **300** of the present invention functions to translate the set of 17 environmental conditions data **120** (including large-scale macroclimatic information) into a 18 description of the microclimates experienced by the animal. The model **300** is based on a 19 basic model (hereinafter referred to as "basic model") previously disclosed as described 20 below, but further incorporates several improvements thereto.

25 The improvements to the microclimate model **300** include the incorporation of a solar 26 radiation model. The solar radiation model enables the input of solar radiation information 27 from the geographic coordinates of a locality, eliminating the need for direct measurements at 28 the site. The solar radiation model also allows for the calculation of solar radiation when the 29 sun is positioned below the horizon. The microclimate model **300** is further improved in 30 being able to calculate the effects of vegetation on the temperature and wind profiles, and the 31 effects of slope on the temperature, as well as enabling a user to select the heights and depths 32 above and below ground at which the microclimates are characterized.

33 The basic model calculates certain key climate variables from basic principles. The 34 basic model is a one-dimensional finite difference model that uses data from the set of 35 environmental conditions data **120** (including air temperature and wind speeds at certain

heights, average annual temperature to specify deep soil temperature, soil properties, humidity at a known height, measurements of solar radiation, and geographic coordinates) to simultaneously solve the heat and mass balance equations for the ground surface and below (solving the equation numerically with an Adams Predictor-Corrector algorithm), and thereby 5 the above- and below-ground microclimates, over specified time intervals (e.g., hourly simulations for the average day for each month of the year for any locality). The basic model also computes wind speed and temperature profiles from the ground surface (for flat surfaces only) to a two meter reference height (i.e. the height where meteorological data are typically measured). Clear sky solar radiation (when the sun is above the horizon) is measured and 10 these values input to the basic model.

Certain of the basic model calculations were disclosed in prior publications. Air temperature and wind speed profile, soil temperature, and soil surface and below boundary conditions calculations, are set forth in Porter *et al.* [1973. *Behavioral implications of mechanistic ecology: thermal and behavioral modeling of desert ectotherms and their microenvironment*. Oecologia 13:1-54. Wind velocity calculation set forth at equation (2) on p.4; air temperature calculation set forth at equation (3) on p. 5; soil temperature calculation set forth at equation (4) on p. 5; soil surface and below boundary conditions are set forth at equations (5) to (11) on p. 6], the disclosure of which is incorporated herein by reference. Available solar radiation calculations when the sun is positioned above the horizon are 15 described in McCullough and Porter [1971. *Computing clear day solar radiation spectra for the terrestrial ecological environment*. Ecology 52(6):1008-1015. Solar radiation is calculated according to the flow chart (Fig. 2) on p. 1013, which refers to the methodology 20 and the various equations used in the calculations employed], the disclosure of which is incorporated herein by reference.

The basic model uses these data, together with information particular to the animal 25 species selected (i.e. average height above ground and its preferred temperature range; both of which are specified in the set of animal characteristics data 190), to calculate the climate boundary conditions for an average individual of the species (including solar radiation, IR fluxes from the sky and ground, air temperature, wind speed, and relative humidity of the air 30 passing over the animal) and the percentage of habitat thermally available to it. The percentage of thermally available habitat is the percentage that allows the animal to stay

within its preferred temperature range, thereby avoiding significant thermoregulatory heat stress costs.

As mentioned above, the microclimate model **300** of the present invention provides an improved version of the basic model including: (1) the incorporation of a solar radiation model; (2) the ability to calculate the effects of vegetation and slope on temperature and wind profiles; (3) the ability to calculate the effects of topography on air temperature profiles over elevation; and, (4) the ability for a user to specify the heights and depths above and below ground at which the microclimates are characterized.

**i. The solar radiation model.**

The microclimate model **300** improves upon the basic model in that it incorporates therein a solar radiation model to calculate the amount of solar radiation incident on the ground. The solar radiation model of the present invention calculates the amount of solar radiation absorbed per unit area of ground, duration of solar radiation on the ground, and spectral quality, if needed. The basic model, by contrast, takes input on solar radiation measured and/or calculated elsewhere.

Data used by the solar radiation model are provided by a database of solar radiation defined by spectral bandwidth energies available above the earth's atmosphere. Current Julian date is used to compute earth-sun distance to adjust solar energy per unit area. Solar radiation at the earth's surface is calculated by the extinction properties of the atmosphere, depth of the atmosphere and geographic coordinates of a locality at a given time. This eliminates the need for direct measurements at a site.

The solar radiation model is also improved in that it accounts for the effects of slope on solar radiation reaching the ground, whereas the former solar radiation calculations assumed flat ground surfaces only. The effects of slope on the amount of solar radiation reaching a surface may be significant. Accounting for those effects increases the model's accuracy in solar radiation calculations, and thereby also calculations based upon them, such as ground and air temperatures.

A further improvement of the solar radiation model is that it is now able to calculate the amount of solar radiation when the sun is below the horizon, enabling more accurate calculations for the amount of solar radiation present when crepuscular animals are active at dusk and dawn.

The solar radiation model and its various improvements are incorporated into the microclimate model **300** as follows.

*Solar radiation dataset.* Solar radiation data used by the solar radiation model component of the microclimate model **300**, are calculated using a database of solar radiation spectral bandwidth energies available above the earth's atmosphere (F.S. Johnson (private communication to inventor, in Ch.1, p.2 of Robinson, N. 1966. Solar Radiation. Elsevier Publ. Co., New York. 347p.). Current Julian date is used to compute earth-sun distance to adjust solar energy per unit area on top of the atmosphere. Solar radiation at the earth's surface is calculated from the extinction properties of the atmosphere (see, McCullough and Porter, 1971, ref. above), depth of the atmosphere and geographic coordinates of a locality and time. Measurements of solar radiation taken at the actual location are no longer required, although they may be used for verification purposes. The database of spectral bandwidth dependent atmospheric extinction coefficients and solar radiation spectral bandwidth energies is contained in a data file, Solar.dat (not shown).

*Effect of slope on solar radiation.* The solar radiation model further improves the basic model by incorporating the effects of slope on the amount of solar radiation reaching the ground. The effects of slope are calculated by equations based on work by Hosmer, G.L. (1910. Practical Astronomy. Wiley & Sons. New York, or Hosmer, G.L. and J. M. Robbins. 1948. Practical Astronomy. Wiley & Sons. 355 pp.). The summary equation is presented in W.D.Sellers (1965. Physical Climatology, University of Chicago Press, 272 pp. Equation No. 3.15 on p. 35), the disclosure of which is incorporated herein by reference).

*Below horizon solar radiation.* The solar radiation model enables the calculation of the amount of solar radiation when the sun is below the horizon, as at dusk and dawn. Prior to this the basic model assumed that the sun was full sun and located above the horizon. Values for below horizon solar radiation enable more accurate measures for the amount of solar radiation in the microclimatic environments of crepuscular animals.

The solar radiation model of the present invention calculates the amount of solar radiation when the sun is below the horizon by first computing the amount of skylight (see, G.V. Rosenberg, 1966. *Twilight*. Plenum Press, pp. 18-19). First, the total lumens are calculated from a regression of data from "Twilight" (which is  $E_{\text{log}} = 41.34615384 - 0.423076923 * \text{Zenith angle}$ ). The sky luminosity is equal to  $10^{**E_{\text{log}}}$ . Lumens/m<sup>2</sup> are then

converted to W/m<sup>2</sup> (see, Documenta Geigy Scientific Tables. 1966. 6th edition. K. Diem, ed., p. 239), by multiplying by the mechanical/electrical equivalent of light (*i.e.*, 1.46\*10<sup>-3</sup> kW per lumen).

5           ii.       **Effects of vegetation on microclimate.**

Vegetation-climate interactions can impact directly and indirectly animal food and water requirements, growth and reproduction potential, activity patterns, population dynamics, and structure of food webs. For example, loss of vegetation in cold climates can be particularly challenging for large animals that depend on intact evergreen vegetation for radiant protection during the cold winter nights that they must endure. The effects of vegetation on an animal's microclimate are calculated by the microclimate model **300** of the present invention.

The microclimate model **300** calculates the effects of vegetation on the temperature and wind profiles from the ground level to a 2 m reference height, including at the animal's average height above ground.

Under dense vegetation, the overhead sky radiant temperature (T<sub>sky</sub>) is assumed to be equal to the local 2 m air temperature (T<sub>air,2m</sub>). The leaves or needles of trees and/or bushes may provide radiant insulation because they generally have high heat transfer coefficients, which causes them to be convectively warmed at night or cooled during the daytime. Multiple layers of vegetation above 2 m may provide further radiant insulation.

Modification of wind velocity profiles by vegetation may be measured empirically. In the absence of such information, the "bushel basket" formula can be used to estimate velocity profiles between objects of known dimensions and distances (C.R. Stearns. 1967.

Micrometeorological studies on the coastal desert of Peru. Ph.D. thesis, University of Wisconsin, Madison, WI).

Whether temperatures between the 2 meter height (T<sub>air,2m</sub>) and ground surface (T<sub>grd</sub>) vary, depends upon the amount of sunlight striking the ground. One extreme is complete shade, which results in no temperature differences between ground and two meters. The other extreme is no shade, which results in a typical logarithmic air temperature profile. Changes in the percent of ground shade alter ground surface temperature, which in turn, alters the temperature profile between the surface and 2m shade temperature. Though vegetation is assumed to alter wind velocity profiles, temperature profiles are currently assumed to be

unaffected by vegetation, except for the degree of ground shade specified by the user.

**iii. Effects of slope on microclimate.**

The amount of solar radiation reaching the ground surface depends on the slope of the ground. Hence an improvement over the prior basic model, is the incorporation of slope into the present microclimate model **300** to improve the accuracy of solar radiation calculations. This is done by equations based on work by G.L. Hosmer (the summary equation is No. 3.15 on p. 35 of *Physical Climatology* by W. D. Sellers. 1965. University of Chicago press. 272 pp., and is incorporated herein by reference).

**iv. Effects of topography on microclimate.**

Topography can affect air temperature profiles over elevation. The present microclimate model **300** is able to calculate those effects by using adiabatic principles to adjust temperatures based on elevation differences from temperatures at a known height. There are various corrections used from 9.9 degrees C. per kilometer in non-mountainous regions, to 5.5 degrees C. per kilometer in mountainous regions. The equation using meters and degrees C. is:

$$\text{current temperature} = \text{reference temperature at reference elevation} + 0.0055 * (\text{reference elevation} - \text{current elevation}).$$

**v. User-specifiable heights and depths.**

The microclimate model **300** has also been improved to allow a user to specify the heights and depths above and below ground at which the microclimates are characterized. The user is thus able to customize the microclimate outputs to increase the accuracy for a particular species, to enable a broader array of scenarios to be posed in order to better manage an animal population, or to achieve any number of other goals. From a knowledge of the animal morphology, the user specifies the animal's average height above ground. The animal height is then used by the program to compute the wind speed and temperature for profiles that the user has specified, by selection of a reference height for the null calculations for an animal at each locality.

**vi. Microclimate model conditions output **400****

The microclimate model conditions output **400** includes the solutions to the heat and mass balance equations for the ground surface and below, the climate boundary conditions experienced by an individual of the animal species selected, and the percentage of habitat

thermally available to it.

Many of the climate boundary conditions calculated by the microclimate model **300** are illustrated in **FIG. 3a**, a diagram of a cross-section of an animal with porous insulation and heat fluxes including uniform heat generation and uniform heat dissipation by respiration.

5 They include the clear sky solar radiation ( $Q_{\text{solar}}$ ), IR fluxes from the sky ( $Q_{\text{IR,sky}}$ ) and ground ( $Q_{\text{IR,grd}}$ ), air temperature at the average height of the animal ( $T_{\text{air}}$ ), ground temperature ( $T_{\text{grd}}$ ), and the wind speed ( $V$ ) and relative humidity (RH) of air passing over the animal at its average height above ground.

10 The percentage of habitat thermally available to the animal is also calculated based on the climate boundary conditions and the specified preferred temperature range of the animal.

### **c. Animal model 500**

15 The animal model **500** of the present invention uses the microclimate conditions output **400** and data included in the set of animal characteristics **170**, to calculate an animal conditions output **600** (see, W.P. Porter *et al.* 2000. *Calculating climate effects on birds and mammals: impacts on biodiversity, conservation, population parameters, and global community structure*. Amer. Zool. 40:597-630). In general, the output **600** includes the values for several energetic variables including total discretionary energy and water, the temperature-dependent activity of the animal and the total annual activity time of the animal. Using the values for these energetic variables, spatial analyses and further calculations **800** may be 20 performed to analyze spatial variation and to solve for a variety of population and community level variables such as survivorship, growth and reproduction.

25 In overview, the animal model **500** calculates the aforementioned energetic variables by performing coupled analyses of heat and mass balance and by calculating the total annual activity time of the animal. Different subroutines of the animal model **500** are employed to perform various aspects of the heat and mass balance analyses and to track activity time of the animal. The subroutines include a porous media model for insulation, an optional appendage model, coupled models of the gut and lungs, and a thermoregulatory model.

30 Many of the subroutines are run in parallel and/or iteratively to solve for the various values that drive the final solutions. Together they enable the animal model **500** to accurately calculate the amounts of discretionary energy ( $Q_{\text{discr}}$ ) and water ( $M_{\text{w,discr}}$ ) from first principles (*i.e.*, rather than regression analyses), thus enabling the accurate calculation of

growth and reproduction under any kind of environmental circumstance, and under any kind of animal property.

Referring to **FIG. 2**, the animal model **500** portion of **FIG. 1** is expanded into a flow chart summary of its basic processes. The following description explains how the various 5 sub-models and other calculations performed by the animal model **500**, contribute to each of the steps indicated in **FIG. 2**.

The heat and mass balance analyses performed by the animal model **500** represent the coupled mechanisms of heat and mass transfer. Referring to **FIG 3b**, coupled heat and mass transfer equations are represented that illustrate how they are used to quantitatively evaluate 10 energetic consequences of environmental interactions (e.g., with climate, disease, toxicants and the like), and to assess energetic constraints on community structure.

The equations shown in **FIG 3b** share common terms in the heat and mass transfer equations for metabolism and evaporation. The equations emphasize that the discretionary mass (Mdiscr) available for growth (M<sub>gr</sub>), reproduction (M<sub>rep</sub>), and fat storage (M<sub>s</sub>), depends upon (1) environmental conditions that affect heat fluxes in the diagonal heat balance equation, (2) mass ingested and absorbed which determines the amount of dry matter and water ingested and absorbed, and (3) metabolic rates and evaporative water losses. Metabolic rates and evaporative water losses are affected by an animal's physiology (e.g., body temperature maintained) and behavior (e.g., microclimates selected, activity levels, locomotor costs to obtain food with distribution that changes, appetite levels and the like).

Heat and mass transfer may occur through the flesh, fat and porous insulation layer (i.e., fur or feather) of animals. Referring to **FIG. 3a**, a diagram of a cross-section of an animal with a porous insulation layer and heat fluxes including uniform heat generation (Q<sub>gen</sub>) and uniform heat dissipation by respiration (Q<sub>resp</sub>) is depicted [W.P. Porter *et al.*, 25 2000. (ref. above), Fig. 2 on p. 602]. The cross-section could represent a torso whose geometry may be approximated by a cylinder, sphere, or ellipsoid, or even a cross section through an appendage, if the heat loss by respiration is removed (see *appendage model* below). There may or may not be porous insulation beyond the skin.

**FIG. 3a** depicts the information needed for the heat and mass balance analyses 30 performed by the animal model **500**. Data needed are provided in the set of animal characteristics data **170** [including, mean length of the fibers (hair or hair-like elements in

feathers); fiber density as a function of depth, fiber diameter, the depth of the insulation, and, if the animal is diurnal and exposed to sunlight, solar reflectivity and transmissivity of the fibers]. Also needed are data from the microclimate conditions **400** that specify the climate boundary conditions for an individual [solar radiation (Qsolar), IR fluxes from the sky 5 (QIR,sky) and ground (QIR,grd), air temperature at the animal's average height (Tair), ground or other surface temperature (Tgrd), and the wind speed (V) and relative humidity (RH) of air passing over the animal at its average height above ground]. The climate boundary conditions are calculated by the microclimate model **300** based on the animal's average height above 10 ground and the microclimate calculations for environmental conditions above ground (see section on microclimate model **300** above).

### **i. Performing the heat balance analysis **501****

Performing the heat balance analysis **501** comprises running a porous insulation model to simultaneously calculate the amount of heat entering the animal from external sources (Qin), and the amount of heat leaving the animal to the environment (Qout), contingent on the current guess for the metabolic heat generation needed to maintain the animal's core temperature (Qgen). Simultaneous calculations are required because in porous media, diffuse radiation fluxes and conduction interact with each other to affect the insulation temperature profile from skin to insulation-air interface. If the core-skin temperature gradient is too small, then a thermoregulatory model **537** is invoked until a stable solution is found that will allow a core-skin temperature gradient of at least 0.5 degrees C to exist.

#### **1. Calculating the amount of solar radiation absorbed by the animal (Qsolar,a) **510**.**

Computing the amount of solar energy absorbed (Qsolar,a), is accomplished as follows.

25 Direct beam solar radiation (Qsolar,dir):

$$Q_{solar,dir} = ABSAN * ASILN * (1.00 - PCTDIF) * Qnorm * (100 - ashade) / 100$$

where,

ABSAN is animal absorptivity,

ASILN is silhouette area normal to the sun,

PCTDIF is percent diffuse solar radiation,

Qnorm is total solar radiation incident on a surface normal to the sun's direct beam, and  
ashade is percent shade on the animal.

5 Diffuse components (sky and substrate) of solar radiation are then calculated as follows:

$$QSOBJ = ABSAN * Fabush * Area * PCTDIF * Qsolar,hor * (100. - ashade) / 100$$

$$QSSKY = ABSAN * Fa,sky * Area * PCTDIF * Qsolar,hor * (100. - ashade) / 100.$$

$$QSRSB = ABSAN * Fa,grd * Area * (1.0 - ABSSB) * Qsolar,hor * (100. - ashade) / 100.$$

$$QSDIFF = QSSKY + QSRSB + QSOBJ$$

where,

QSOBJ is incoming diffuse radiation reflected by an object nearby,

Fabush is the configuration factor between the animal and the nearby object,

Qsolar,hor is the incoming solar radiation on a horizontal surface,

QSSKY is the diffuse solar radiation from the sky (*i.e.* solar radiation scattered by molecules in the atmosphere and by clouds),

Fa,sky is the configuration factor between the animal and the sky

QSRSB is the incoming solar radiation reflected from the substrate (*i.e.* ground or other surface),

Fa,grd is the configuration factor between the animal and the ground,

ABSSB is the absorptivity of the substrate, and

QSDIFF is the total amount of diffuse solar radiation.

25  
20  
15  
Total solar energy absorbed (Qsolar,a) is then calculated as the sum of energy absorbed on the top (*i.e.* dorsal; Qdorsl) and bottom (*i.e.* ventral; Qventr) parts of animal 510.

$$Qdorsl = (QSDIR + QSOBJ + QSSKY)$$

Qventr = QSRSB

Qsolar,a = Qdorsl + Qventr

5                   **2. Estimating the metabolic heat generation needed to maintain the animal's core temperature (Qgen) 520 and computing the temperature of the skin (Tskin) 530.**

10                  An estimate for the metabolic heat generation needed to maintain the animal's core temperature (Qgen) is made 520. Before calling the iterative guessing routine, Zbrent, the iterative guessing routine two bounding guesses are needed to start the process. This is done by first guessing for total metabolic rate (W) using the standard regression value in the literature for an animal at 28 C air and radiant temperature, humidity approximately 5%, and low wind speed, approximately 0.1 m/s. Humidity and wind speed were never reported for the experiments. MASS is in kg. The regression units are not J/s, so conversion is required.

15                  
$$Q_{gen} = X1 = (70. * MASS^{0.75}) * (4.185 / (24. * 3.6))$$

20                  A second guess is created by arbitrarily adding 5 to the value of X1 just calculated. A stability check is done on the value of X1 to make sure it does not equal zero. Then a bracketing subroutine, ZBRAC, (Press, W. H., Flannery, B .P., Teukolsky, S.A., and Vetterling, W. T.. 1987. Numerical Recipes. The Art of Scientific Computing. Cambridge University Press, Cambridge ) is called.

25                  CALL ZBRAC(FUN,X1,X2,SUCCES)

                FUN is the name of the function containing the energy balance equation, X1 and X2 are two starting guesses, SUCCES returns a value indicating success of the process.

                A criteria for success, TOL, in balancing the energy balance equation must be specified. Ideally TOL equals zero if heat fluxes in and generated in exactly equals heat fluxes out.

                In the program TOL = 0.01\*mass

                Then a solution is sought by invoking the energy balance equation via ZBRENT (Press et al., ibid.) and FUN.

$$Q_{gen} = ZBRENT(FUN,X1,X2,TOL)$$

                Inside FUN the estimated value for Qgen is then equated to the value for the heat generation per unit volume (g ),

$$g = Q_{gen} / VOL$$

Respiratory water loss as a function of oxygen consumption is then done based on the heat generation requirement. No negative metabolic rates are allowed.

If (Qgen .gt. 0.000) then

CALL RESP

5 else (Negative metabolic rate. No physiological meaning – set dummy values  
this guess)

Qresp = 0.00000

Qgen = -10.00000

endif

10 Net internal heat generation is calculated as

Qgenet = Qgen - Qresp

Net internal heat generation/unit volume is then calculated.

Gn = Qgenet/Vol

This is used for estimating skin temperature as in Eq. (53) (Porter *et al.*, 1994, at p. 162,

15 herein incorporated by reference):

$$Gn = g = [(n K) / R^2] * (Tcore - Tskin)$$

where,

n is the geometry constant (varies with shape),

K is the thermal conductivity for tissue,

R is the radius of the animal,

Tcore is the core temperature of the animal, and

Tskin is the skin temperature of the animal.

Rearranging the equation, the Tskin is solved for 530. The value for Tskin is then

25 used in subsequent calculations.

### 3. Computing heat fluxes between the animal and its environment 540.

The heat fluxes occurring between the animal and its environment are calculated by solving for the amount of heat exchange across the insulation of the animal using a porous insulation model to compute both the amount of heat entering the animal and the heat losses 30 541 from the animal. An appendage model is also employed in the case of large birds and mammals to further incorporate heat fluxes across an animal's appendages.

a.) The porous insulation model.

The porous insulation model of the present invention is run to calculate the amount of heat exchange across the insulation of the animal ( $Q_{in} - Q_{out}$ ). For birds and mammals greater than 100 kg in size, an appendage model (see below) is also employed to more 5 accurately calculate the heat exchange over appendage surface areas.

Unlike the prior version of the porous insulation model [W.P. Porter *et al.*, 1994.

*Endotherm energetics: from a scalable individual-based model to ecological applications.* Aust. J. Zool. 42:125-62, Appendix equations (24) to (53) on pp. 159-162 and description of the model and methods on pp. 127- 137, the disclosure of which is incorporated herein by 10 reference], the porous insulation model of the present invention incorporates a solar radiation calculation to broaden its applicability to daylight conditions. In this way, the porous insulation model enables a user to calculate the amount of  $Q_{in}$  including both when the animal is exposed to sunlight and when the animal is in the dark.

Solar radiation ( $Q_{solar}$ ) is incorporated into the porous insulation model by assuming that solar radiation is absorbed very close to the fur/feather-air interface, which is usually the case for bird feathers and dark, dense fur. Absorbed solar radiation ( $Q_{solar,a}$ ) heats the fiber elements, which then emit infrared radiation outward ( $Q_{IR,out}$ ) toward the sky and inward ( $Q_{IR,in}$ ) through the porous insulation. The watts of absorbed solar radiation ( $Q_{solar,a}$ ) are treated as an additional source of thermal radiation from the sky for the half of the animal exposed to the sky. Thus, the diffuse IR equations already in the prior model were also used for incorporating absorbed solar radiation in the model of the present invention. To do this, an additional term for absorbed solar radiation was added to equation (52) of the original model (Porter *et al.*, 1994, eq. (52) at p. 162).

25 Computing IR fluxes in. The Swinbank formula is applied to solve for the clear sky temperature ( $T_{sky}$ ) in degrees Kelvin, based on the air temperature at 2 m in height ( $T_{air,2m}$ ) in degrees centigrade.

$$T_{sky} = 0.0552 * (T_{air,2m} + 273.)^{**}(1.5-273.)$$

30 IR fluxes from other objects overhead of the animal (*i.e.* vegetation) that are ‘substituting’ for sky, are also calculated. The temperature of vegetation ( $T_{veg}$ ) is set to the

Tair,2m to solve for the IR fluxes from sky (QIR,sky) and vegetation (QIR,veg):

$$T_{veg} = T_{air,2m}$$

$$QIR,sky = C3 * (T_{sky} + 273.15)^{**4}$$

$$QIR,veg = C6 * (T_{veg} + 273.15)^{**4}$$

5 Next, the porous media model checks for whether fur or feathers are optically thick or not. If optically transparent [*i.e.* no effective fur or feathers or no insulation present (as is the case for many ectotherms)], it is assumed that no solar radiation is absorbed by the fur or

10 feathers. If, on the other hand, the fur or feathers are optically thick, solar radiation is treated as though it is absorbed close to the fur-air interface and is treated as an IR source.

15 IF(B1ARA(1) .lt. 0.001), then fur/feathers optically transparent (no effective fur) and,

$$QIR,above = QIR,sky + QIR,veg$$

$$QIR,below = sig * (T_{grd}(i) + 273.15)^{**4}$$

where,

20 B1ARA(1) is a variable that indicates the optical thickness of the fur or feathers; it is the exponent of Beer's Law (*i.e.* the extinction coefficient ( $\tau$ )times the depth of fur/feathers ( $t$ )),

QIR,above is the IR fluxes from above the animal,

QIR,below is the IR fluxes from below the animal,

sig is the Stefan-Boltzmann constant, and

25 Tgrd(i) is the ground temperature at location (i).

Else, optically thick, fur present and solar radiation absorbed, qdorsl from above and qventr (solar reflected from the ground) is treated as diffuse radiation absorbed by the fur,

$$QIR,above = QIR,sky + QIR,veg + qdorsl$$

$$T_{sky} = (QIR,sky / (C3+C6))^{**0.25} - 273.15$$

$$QIR,below = sig * (T_{grd} + 273.15)^{**4} + qventr$$

$$T_{grd} = (QIR_{,grd} / \text{sig})^{**0.25} - 273.15$$

Whichever the case, the amount of radiant heat entering the animal from external sources (QIR,in) is:

5                     $QIR_{,in} = QIR_{,above} + QIR_{,below}$

as illustrated in FIG.3a.

*Computing heat losses via conduction, convection, evaporation and IR flux. 541.*

Equation (52) of the original model (Porter *et al.*, 1994. eq. (52) at p. 162, see PP. 156-169 for explanation of variables) is:

10

$$C1 = - [4\sigma ((T_{skin} + T_{sky}) / 2)^3 (T_{skin} - T_{sky})(1 - 2E_3(\beta_T Z_L)) + h_c(T_{skin} - T_{air}) + 2\sigma(T^4_{skin} - T^4_{sky})E_3(\beta_T Z_L)] / [(k_{eff} + k_r) + (h_c + 2\sigma((T_{skin} + T_{sky}) / 2)^3 (1 - 2E_3(\beta_T Z_L))) Z_L]$$

15                    In the new version (Porter *et. al.*, 2000), the equation has been modified so that the sky, the ground, and nearby objects (bush, boulder, etc.) are treated separately and then combined. The equations have been normalized for more compact form.

The sky portion of radiant heat exchange (TAVsky) is,

20

$$\begin{aligned} TAV_{sky} &= ((T_{sky} + T_{skin}) / 2.) + 273.15 \\ KRADSKY &= (16.0 * \text{sig} * TAV_{sky}^{**3.}) / (3. * \text{BETARA}(2)) \\ HR &= F_{a,sky} * 4. * \text{EMIS} * \text{sig} * (T_{sky} + 273.15)^{**3} \\ BIR &= HR * ZFURAR(2) / (\text{KEFARA}(2) + KRADSKY) \\ BICV &= HC * ZFURAR(2) / (\text{KEFARA}(2) + KRADSKY) \\ D1 &= 1. + BICV + 2. * BIR * (0.5 - (0.333 - E4B1 / B1ARA(2))) \\ C1N &= (BICV * (1. - T_{air} / T_{skin}) + BIR * (1. - T_{sky} / T_{skin})) \\ C1dors &= C1N/D1 \\ PSI &= 0.854 + (\text{ALOG10}(BICV) * 0.149) \\ QRADSK &= PSI * \text{Areaskin} * F_{a,sky} * KRADSKY * (C1dors * T_{skin} / ZFURAR(2)) \end{aligned}$$

where,

TAVsky is the average temperature on the dorsal half of the animal  
(degrees K),

KRADSKY is the fur/feather radiant conductivity in the sky direction,

5 BETARA(2) is the IR extinction coefficient of fur/feathers,

HR is the radiant heat transfer coefficient,

EMIS is the emissivity of the animal,

BIR is a dimensionless variable for IR heat transfer,

BICV is a dimensionless variable for convection heat transfer,

10 ZFURAR is the depth of fur,

KEFAR is the effective thermal conductivity of fibers and air for  
conduction,

HC is the convection heat transfer coefficient,

D1 is dimensionless,

C1N (C1 normalized) is dimensionless,

PSI is a correction factor,

TKair,TKskin, TKsky are the temperatures of air, skin, sky in degrees  
K,

20 QRADSK is the incoming solar IR radiation from the sky through the  
porous media,

Tskin is the skin temperature of the animal, and

Subscript notation: (1) = overall, (2) = dorsal, (3) = ventral fur

The following calculations continue in the same way as those above, but for a bush or

25 nearby large object portion of radiant heat exchange, instead of for sky (definitions above are  
easily substituted for variables below with respect to bush instead of sky and will not be  
defined separately):

$$TAVbsh = ((Tbush + Tskin) / 2.) + 273.15$$

$$30 \quad KRADBUSH = (16.0 * SBK * TAVbsh **3.) / (3. * BETARA(2))$$

$$HR = Fabush * 4.* EMIS * SBK * (Tbush + 273.15)**3$$

$BIR = HR * ZFURAR(2) / (KEFARA(2) + KRADBUSH)$   
 $BICV = HC * ZFURAR(2) / (KEFARA(2) + KRADBUSH)$   
 $D1 = 1. + BICV + 2.* BIR * (0.5 - (0.333 - E4B1 / B1ARA(2)))$   
 $C1N = (BICV * (1. - TKair / TKskin) + BIR * (1. - Tkbush / TKskin))$   
5            $C1bush = C1N / D1$   
 $PSI = 0.854 + (ALOG10 (BICV) * 0.149)$   
 $QRADBU = PSI * Areaskin * Fabush * KRADBUSH * (C1bush * Tkskin / ZFURAR(2))$

10           The ground portion of radiant heat exchange (ventral part of animal),

$TAVgrd = ((TGRD + Tskin) / 2.) + 273.15$   
 $ktop = 16.0 * SBK * TAVgrd^{**3.}$   
 $kbottom = 3. * BETARA(3)$   
 $KRADGRD = ktop / kbottom$   
 $HR = Fa,grd * 4.* EMIS * SBK * (((T2 + Tskin) / 2.) + 273.15)^{**3}$   
 $BIR = HR * ZFURAR(3) / (KEFARA(3) + KRAD)$   
 $BICV = HC * ZFURAR(3) / (KEFARA(3) + KRAD)$   
 $D1 = 1.+ BICV + 2.* BIR * (0.5 - (0.333 - E4B1 / B1ARA(3)))$   
 $C1N = (BICV * (1. - TKair / TKskin) + BIR * (1. - TKgrd / TKskin))$   
 $C1vent = C1N / D1$   
 $PSI = 0.854 + (ALOG10 (BICV) * 0.149)$   
 $QRADGR = PSI * Areaskin * Fa,grd * KRADGRD * (C1vent * Tkskin / ZFURAR(3))$

25

The net radiant heat exchange (QRAD) is then the net radiant fluxes between the animal and the sky, ground and bushes (or other objects), *i.e.*  $QRAD = QIR,in - QIR,out$  (in **FIG3a**).

30

$QRAD = QRADSK + QRADGR + QRADBU$

Conduction not lost by outward radiation from hairs within the fur equals convection at fur-air interface (Qconv).

Dorsal conduction (QcondD) (via air (Qcond,air) and fur/feathers(Qcond,hair)):

5                    
$$Q_{condD} = \text{PSI} * (\text{Areaskin} / 2.) * \text{KEFARA}(2) * (C1dors * \text{TKskin} / \text{ZFURAR}(2))$$

Ventral conduction (QcondV) (via air (Qcond,air) and fur/feathers(Qcond,hair)):

10                  
$$Q_{condV} = \text{PSI} * (\text{Areaskin} / 2.) * \text{KEFARA}(3) * (C1vent * \text{TKskin} / \text{ZFURAR}(3))$$

Total heat loss by conduction (Qcond) is then:

15                  
$$Q_{cond} = Q_{condD} + Q_{condV}$$

20                  
$$C1 = (C1dors + C1vent)/2.$$

The fur energy flux (Qfur) is the total heat loss from the skin and fur.

25                  
$$Q_{fur} = Q_{cond} + Q_{IR,out} + Q_{evap,skin} + Q_{conv}$$

The whole animal energy balance at the skin is then,

30                  
$$Q_{net} = Q_{in} + Q_{gen} - Q_{out}$$

where,

$Q_{net}$  is the net heat exchange of the whole animal;

$Q_{in}$  is the total energy entering the animal =  $Q_{solar,a} + Q_{IR,in}$ ;

30                   $Q_{gen}$  is the metabolic heat generation needed to maintain the animal's core temperature (estimated earlier in the process); and,

Qout is the total energy leaving the animal = Qfur + Qevap,resp (where Qevap,resp is calculated below by the lung model as part of the mass balance analysis).

5 *Computing the ERROR by solving the heat balance equation 550.* Assuming that the value of Qnet will approach 0 when the value of Qgen is accurate, the ERROR is substituted for Qnet in the equation and solved for as follows,

$$\text{ERROR} = \text{Qin} + \text{Qgen} - \text{Qout}$$

10

The actual value of ERROR is then compared to the user-specified maximum acceptable value for Error, TOL, 555. If the actual ERROR is greater than the specified value, a new estimate for Qgen is generated 520 and a new value for Tskin is calculated 530 for subsequent use in the following computations of heat losses 540.

15 If the ERROR is less than or equal to the specified maximum value, the value of Qgen is deemed to be accurate, and the value for Tskin previously calculated on its basis 530 is also deemed accurate. In that case, the thermoregulatory model 537 is actuated (see below) and a calculation of the core-skin temperature gradient (Tcore-Tskin) is made and compared to a user-specified value (for example, 0.5 degrees C).

20 If the core-skin gradient is less than 0.5 C, the animal must respond behaviorally or physiologically to enable proper cooling. In this case, the thermoregulatory model 537 invokes the behavioral and physiological options in a predetermined order. After an option is chosen, the animal model 500 proceeds to estimate the Qgen 520 and proceed through the aforementioned steps until evaluating the core-skin temperature gradient again. If the 25 gradient is still not satisfied, the next option is set and calculations repeated until the minimum core-skin gradient is satisfied.

When the core-skin temperature gradient is satisfied, (*i.e.*, it is greater than or equal to 0.5 C), the animal is assumed to be able to cool itself properly. The animal model 500 then proceeds to begin another round of calculation over every other hour of a day to calculate an 30 average day of each month, then over every month to eventually calculate annual values for the various energetic variables.

**b.) The appendage model.**

An appendage model was also added to the animal model **500** to more accurately calculate the amount of heat entering and lost from the animal via its appendages when the model is applied to large birds (such as, for example, the rhea, the cassowary, and the ostrich) 5 and to mammals of a size greater than or equal to 100 kg. As applied to those sorts of animals, the appendages are large and may constitute a significant percentage of the surface area of the standing animal over which heat may be gained or lost. The geometries used to model a large standing bird (cylinders and ellipsoid) compared to a sitting bird (ellipsoid) vary accordingly. But without porous insulation and respiratory water loss, the appendage 10 model is used to calculate heat loss in the radial dimension from the appendages of an animal.

**c.) The thermoregulatory model **537**.**

The thermoregulatory model yields modified microclimate/physiology conditions that allow for a stable solution for body temperature when there is heat stress (*i.e.*, when the core-skin temperature gradient ( $T_{core}-T_{skin}$ ) is less than 0.5 degrees C, as discussed above). The thermoregulatory model **537** solves for the behavioral and/or physiological changes needed to maintain the animal's core temperature in heat stress conditions.

Options in a behavioral and physiological options hierarchy are chosen sequentially. Initially, the animal model **500** begins by assuming the animal is in a "null" condition. The "null" condition is user-specified and represents a circumstance where the animal is exposed to the sun and sky as much as possible given user specified constraints (*e.g.*, regarding whether the animal is diurnal, nocturnal or crepuscular; whether it is arboreal or fossorial; the percent shade available and degree of cloud cover in the animal's environment; and the like).

If the core/skin gradient is not greater than or equal to the specified minimum (*e.g.*, 0.5 degrees C), then the thermoregulatory model's **537** options hierarchy is invoked. In the first 25 level, the animal may proceed to modify its behavior by, for example, seeking shade on the ground, climbing to cooler temperatures in the shade, retreating below ground, or acting otherwise depending on the user specified behavioral options. Option-dependent values for variables are set and the animal model **500** proceeds to begin again to estimate  $Q_{gen}$  **520** and following (as described above, *see FIG. 2*) until the core-skin gradient is once again evaluated. If the chosen option is insufficient to maintain at least the minimum core-skin 30 gradient, then the next behavioral option is exercised, and so on through the behavioral

options until the minimum core/skin temperature gradient is satisfied.

If the behavioral options fail to satisfy the minimum core-skin temperature gradient, then the animal is allowed to exercise physiological options and the model iterations repeated as with the behavioral options. The user may specify that the animal first allow its core temperature to rise before invoking evaporative heat loss, or alternatively, the user can specify that the animal invoke evaporative heat loss first and, failing that, allow its core temperature to rise. A core temperature increase will always allow for a stable solution and may be exercised as a last option.

Many different and varied combinations of behavioral and physiological options are possible and specifiable by the user. Each will generate its own set of energetic costs that will subsequently feed into the animal model's **500** calculation of the amount of discretionary energy and water. The thermoregulatory model's **537** evaluation of the behavioral and physiological options available to an animal may yield significant insights into how best to manage the environment of an animal for minimal stress, optimal activity time and other related effects.

## **ii. Performing the mass balance analysis **502****

The mass balance analysis of the present invention solves for the amount of discretionary mass from food ( $M_{f,discr}$ ) [given the amount of food needed to meet the metabolic heat generation required to maintain the animal's core temperature ( $Q_{gen}$ )], the amount of discretionary mass from water ( $M_{w,discr}$ ), and the amount of discretionary energy ( $Q_{discr}$ ) available to the animal.

The mass balance equations of the animal model **500** generally solve for the total discretionary mass from food and water ( $M_{discr}$ ) by calculating the mass of food and water absorbed by the animal ( $M_{f,a}$ ,  $M_{w,a}$ ) [equaling the mass of food and water intake by the animal ( $M_{f,i}$ ,  $M_{w,i}$ ) minus the mass of food and water loss by excretion and evaporation ( $M_{f,d}$ ,  $M_{w,u}$ ,  $M_{w,evap}$ )], and the mass of food and water metabolized by the animal ( $M_{f,met}$ ,  $M_{w,met}$ ). To do this, the animal model **500** employs molar balance models for the lungs **570** and gut **560** to allow for the coupling of food ingested and/or absorbed to respiratory gas exchanges and evaporative water loss from the respiratory system.

One of the improvements in the animal model **500** is the addition of the distributed respiratory water loss, which represents lungs that span most of the body cavity. This

innovation gives much better agreement of predicted metabolic rates with measured values. A skin subroutine is also used to calculate evaporative water loss from skin (Mw, evap, skin).

### 1. Solving for the amount of discretionary mass from food (Mf,discr).

#### 5 a.) The gut model 560.

The gut model **560** couples food ingested to respiratory gas exchanges and evaporative water loss from the respiratory system. **FIG. 4** shows the system diagram for the molar balance gut model **560**. It is related to the well-known batch reactor and plug flow model originally developed in chemical engineering and subsequently applied to animal digestive systems (see, Penry, D.L. and P.A. Jumars, 1987. *Modeling animal guts as chemical reactors*. Am. Nat. 129:69-96). The model used in the present invention allows for any type of ingested food consisting of user specified proportions of carbohydrates, lipids, proteins and water content. The food can enter the gut any time during activity time in any amount, subject to the constraint that the volume of food ingested per day may not exceed the wet mass of the animal. The energy value of absorbed carbohydrates, lipids, and proteins is well known (see, Schmidt-Nielsen, K. 1979. *Animal physiology, adaptation and environment*. 2d ed., Cambridge Univ. Press, Cambridge, MA).

10 The gut model **560** determines an upper bound for absorbed food. It does not explicitly consider important constraints on food intake that are affected by how food is distributed in the environment, which affects encounter probability, and what the handling time is, which is a function of feeding apparatus morphology. Both encounter probability and handling time may affect how much food is actually ingested. The present version of the gut model waits until a 24 hour activity simulation cycle starting at midnight has been completed. Then it looks back at the day's energy requirements and uses that to calculate how much of 15 the food would have to be processed in the gut that day to meet those demands. Other cycle lengths could be used instead, depending on the user's interests.

20 The user specifies the food properties. They include percent of proteins, carbohydrates, lipid, and percent dry mass relative to wet mass. There is an upper bound constraint that the animal may never consume more wet weight food per day than its body 25 mass.

The gut model **560** deals only with the part of the gut associated with the actual digestive process. Handling time and internal storage of food in the stomach(s) is not considered. These will place additional constraints on gut function. Because retention time may vary from approximately one-third of a day to more than a day, depending on body size, 5 a day's energy requirements and the mass flow of food per day needed to meet those requirements are used. The total energy requirements are set to some factor of the energy needed to maintain core temperature on any particular day simulated. For example, the total energy requirements may be set to equal 3.5 times the energy needed to maintain the animal's core temperature on a particular day.

10 A digestive efficiency is set to a value depending on food type. For example, a digestive efficiency of 57% has been measured for seeds in small rodents and is very close to the value for digestive efficiency by cattle (61%). The model requires empirical data on digestive efficiency and food properties as defined above (these data are typically provided by the user but may instead be provided by the animal characteristics database **190** if appropriate data are contained therein). The gut model **560** assumes that the gut can alter flow rates to maintain the same digestive efficiency for a particular type of food.

15 Animals typically do not overeat or gain weight unnecessarily. The gut model **560** assumes that the amount of food ingested is determined by today's metabolic needs and is constrained by maximum volumetric flow rate less than or equal to body mass. The user defines percent digestive efficiency, percent water in feces, percent urea in urine, and a multiplier from 1 to 7 (timbas) above basal metabolic energy requirements to specify food intake to meet current needs. The user also defines percent protein, percent fat, percent carbohydrate, and percent dry matter in ingested food.

20 The dry grams of food needed to meet the metabolic demand are estimated based on food properties and the constraints specified above.

25 The gut model **560** is related to work by Penry and Jumars (1987, ref. above, incorporated herein by reference). Their equation (9), p. 73, for a batch reactor model is:

$$\text{time} = CA_o \int_0^{X_{af}} (d X_A / -r_A)$$

where

30  $X_A$  = mole fraction of species A (dimensionless)

$$X_A = (CA_o - CA) / CA_o$$

CA = food component, A, concentration (moles)

CA<sub>0</sub> = initial concentration of food component, A, in moles.

Many of the components of reactor models are not known. Since the endotherm  
5 thermoregulatory model (described in previous section) can calculate metabolic heat  
production to maintain a specified core temperature (Qgen), it is straightforward to calculate  
the grams dry weight, and then wet weight of user-defined food to meet the metabolic  
demand. The following pseudo-equations are an example of these calculations for a seed diet  
by way of illustrating the method.

10 The amount of fat, protein, and carbohydrate per gram dry mass of food (gfatpg,  
gprotpg, gcarbpg, respectively) is first computed from user specified percentages of these  
components of food (pctfat, pctpro, pctcar, respectively), as in:

15  $gfatpg = pctfat \text{ (g fat / g dry mass)}$

$gprotpg = pctpro \text{ (g protein / g dry mass)}$

$gcarbpg = pctcar \text{ (g digestible carbohydrate / g dry mass)}$

$gsum = gfatpg + gprotpg + gcarbpg$

20 Next undigested mass per gram dry mass of food (gundig) is calculated and used to  
compute total carbohydrates (TOTCARB):

gundig = 1.00 - gsum

$TOTCARB = gcarbpg + gundig$

25 Then joules per gram dry food (TotJpgram) is calculated:

$fatJpg = gfatpg * (9400. * 4.185) \text{ (g fat / g dry food * calories / g fat *}$   
J/calorie)

$protJpg = gprotpg * (4199 * 4.185)$

30  $carbJpg = TOTCARB * (4200. * 4.185)$

$TotJpgram = fatJpg + protJpg + carbJpg$

Not implemented here is the variable protein digestion efficiency (DigEff) for ruminants versus monogastrics (approximately 75% vs. 13%). While proteins are important from a protein and amino acid balance standpoint, in terms of absolute energy available, it is a small factor, since alfalfa (reference number 100056) vs. grass forage (reference number 102250) varies from approximately 8.6% protein to 18.1% protein (US-Canadian nutrient compound composition tables, 1994). Seed protein is 15% (see, Kelrick, M.R. and J.A. MacMahon, 1985. *Nutritional and physical attributes of seeds of some common sagebrush-steppe plants: some implications for ecological theory and management*. J. Range Manage. 38(1):65-69 ).

Calculation of joules absorbed per gram of dry food (Jabsngr) is:

$$Jabsngr = fatJpg + protJpg + DigEff * carbJpg$$

The moles available/g dry food (Totmolpg) can now be calculated:

$$Totmolpg = gfatpg * 850 + gprotpg * 137 + gcarbpg * 180$$

The joules of chemical energy needed to be absorbed by the gut /day (FoodJ) = joules per second (J/s) \* seconds/hour (s/h) \* 24 hours/day \* basal multiplier for metabolic rate (i.e., activity above resting; timbas), can then be calculated:

$$FoodJ = Qmetab J/s * 3600 s/h * 24 h/d * timbas$$

The dry mass needed to be absorbed per day to meet the metabolic demand is then,

$$DRYA = FoodJ/Jabsngr$$

The grams of dry food that must be ingested per day (Drymas) and then the total moles of each of the foodstuffs (Totmoles) are calculated:

$$\text{Drymas} = \text{DRYA} / (1.0 - \text{gundigest})$$

Total moles available for absorption = moles/dry gram \* dry grams

$$\text{Totmoles} = (\text{gfatpg} * 850. + \text{gprotpg} * 137 + \text{gcarbpg} * 180.) * \text{drymas}$$

5 The joules of food needed in the gut per day to meet resting metabolism plus user specified activity level = (J/DAY)\*basal multiplier:

$$\text{FoodJ} = \text{DaysMETAB} * \text{timbas}$$

10 The needed grams of food absorbed per day = J needed/day / Food J/g :

$$\text{DRYABS} = \text{FoodJ} / \text{Jabspg}$$

The grams dry food ingested per day = g absorb/DigEff:

$$\text{Drymas} = \text{DRYABS} / (1.0 - \text{gundigest})$$

$$\text{Wetmas} = \text{Drymas} / \text{PctDry}$$

15 The program band tests for whether the required food mass per day exceeds body mass. If it does, absorbed mass is reset to the maximum value allowed by body weight and energy available is adjusted accordingly.

$$\text{Upplim} = \text{Gmass}$$

If (Wetmas .greaterthan. Upplim), then

25                     $\text{Wetmas} = \text{Upplim}$

$$\text{Drymas} = \text{Wetmas} * \text{PctDry}$$

$$\text{DRYABS} = \text{Drymas} * \text{DigEff}$$

$$\text{Jpdaymax} = \text{DRYABS} / \text{Jabspg}$$

$$\text{Jpsavail} = \text{Jpdaymax} / (24.* 3600.)$$

30                    Endif

Once it is known that the upper bound has not been exceeded, the day's joules of energy absorbed (DaysJabs) can be calculated.

$$\text{DaysJabs} = \text{Jabsppgr} * \text{DRYABS}$$

5 The energy available, Avlnrg, in joules/s available can be calculated

$$\text{Avlnrg} = \text{DaysJabs} / (24.*3600.)$$

The g wet weight through the gut/day is then calculated (CRTOT) to monitor part of the water balance of the animal:

10

$$\text{GW} = (\text{Drymas} - \text{PCTDRY} * \text{Drymas}) / \text{PCTDRY}$$

$$\text{CRTOT} = \text{gw} + \text{Drymas}$$

15 The hourly dry grams absorbed of protein, fat and carbohydrate (GPROTH, GFATH, GCARBH, respectively) are also tracked for use in the growth model (see, Adolph and Porter, 1996. ref. above).

$$\text{Dryinphr} = \text{DRYABS} / 24.$$

$$\text{GPROTH} = \text{Dryinphr} * \text{gprotpg}$$

$$\text{GFATH} = \text{Dryinphr} * \text{gfatpg}$$

$$\text{GCARBH} = \text{Dryinphr} * \text{gcarbpg}$$

20

25

Size dependent constraints appear when the energy (mass) needs for the day exceed the daily gut volume flow rate for the body size. Available activity time available is calculated. That can be used to back calculate required handling time of the food needed to meet the energetic demands and to estimate time efficiency of mass/energy acquisition for all body sizes for a given food type and configuration.

The model assumes 0.40 g water/g protein oxidized (*from*, Hainsworth, F.R. 1981. Animal physiology. Addison-Wesley Publ. Co., Reading, MA).

15 *Proteins.* The approximate gram molecular weight of amino acids is 137 g/mole based on an average over all 22 amino acids (based on information from the CRC Handbook of Chemistry & Physics (1996)).

20 *Lipids.* Data from Guyton (Guyton, A.C., 1991. *Textbook of medical physiology.* 8<sup>th</sup> ed., W.B. Saunders, Philadelphia, PA) are used. The gut model assumes that triglycerides are used for energy. They are stearic acid (880 g/mol), oleic acid (879 g/mol) and palmitic acid (754 g/mol). Based on these data the model assumes as an average 850 g/mol. The model uses 4.7 calories/ml O<sub>2</sub> which is 9400 calories/g fat (see, Kleiber, 1975. *The fire of life. An introduction to animal energetics.* 2d ed. Krieger Publ. Co., Huntington, NY). There are 1.07 g water produced/g lipid oxidized (see, Hainsworth 1981, ref. above).

25 *Carbohydrates.* The model assumes that glucose data values are 180 g/mol; 5.0 cal/ml O<sub>2</sub>; 4200 calories/g (see, Kleiber 1975, ref. above) and that there are 0.56 g water produced/g carbohydrate oxidized (see, Hainsworth 1981, ref. above).

30 Digestion capability data used by the model come from several sources (see, Weiner, J. 1987. Limits to energy budget and tactics in energy investments during reproduction in the Djungarian hamster, Phodopus sungorus sungorus, Pallas 1770, in Reproductive energetics in mammals. Symp. Zool. Soc. London 57:167-187; Kenagy, G.J. et al. 1989. Energy requirements for lactation and postnatal growth in captive golden mantled ground squirrels. Physiol. Zool. 62:470-487; Peterson, C.C. et al. 1990. Sustained metabolic scope. Proc. Natl. Acad. Sci. 87(6):2324-2328). Seed component values come from Kelrick and MacMahon (1985, ref. above).

## **2. Solving for the amount of discretionary mass from water (Mw,diser).**

35 Calculating the discretionary mass from water (Mw,diser) requires running the gut model **560** to calculate the mass of water absorbed (Mw,a). The lung model **570** calculates respiratory water loss and the skin evaporation model (*i.e.* the skin subroutine) computes water lost by evaporation due to convection. The difference between water absorbed and water loss is the discretionary water (Mw,diser). Water excreted in urine (Mw,u) is calculated based on the amount of protein in the diet (see below). As mentioned above, an improvement in the animal model **500** of the present invention is the addition of the distributed respiratory water loss, which represents lungs that span most of the body cavity. This innovation gives much better agreement of predicted metabolic rates with measured

values and is achieved by use of the lung model **570**.

**a.) The lung model 570.**

This subroutine is a molar balance for computing water loss from breathing. It uses the oxygen demand for maintaining a user-specified core temperature to compute the amount 5 of air in and out of the lungs. The temperature of the exhaled air relative to ambient air temperature is assigned by the user. This is typically anywhere from 1-3 ° C higher than ambient air. This in effect allows for recovery of water used to saturate air in the lungs, because air leaving the nares is assumed to be saturated at the exhaled air temperature.

Below are the basic calculations performed by the lung model **570**.

10 The partial pressure of oxygen at current conditions is,

$$PO_2 = BarPrs * PCTO_2$$

where,

BarPrs is barometric pressure (pascals)

15 PCTO<sub>2</sub> is the percent O<sub>2</sub> in air

PO<sub>2</sub> is the partial pressure of O<sub>2</sub> (pascals)

The partial pressure of oxygen at standard temperature and pressure (STP) is

$$RefPO_2 = 101325 * RpctO_2$$

20 The lung model **570** calculates the total heat production needed to maintain a user-specified core temperature (Qgen), given the current environmental conditions and the animal's characteristics. Oxygen consumption is based on the calculated heat generation 25 estimate to maintain body temperature (Qgen), corrected for substrate utilized and is calculated as follows:

30 Liters of O<sub>2</sub> per second at STP: (using data for equivalencies from Kleiber 1975, see ref. above)

if (RQ .eq. 1.0) then,

carbohydrates are worth 4200 cal/g  
liter(STP)/s = J/s / ((cal/J) \* (kcal/cal) \* (liters O<sub>2</sub>/kcal))  
O<sub>2</sub>STP = Qgen \* Timbas / (4.185 \* 1000 \* 5.0)

else

5 if (RQ .le. 0.7) then,

fat; fat's worth 9400 cal/g  
O<sub>2</sub>STP = Qgen \* Timbas / (4.185 \* 1000 \* 4.7)

else

protein (RQ=0.8); proteins worth 4300 cal/g on average  
10 O<sub>2</sub>STP = Qgen \* Timbas / (4.185 \* 1000.\* 4.5)

where,

Timbas is the basal multiplier

Qgen is the current guess for total heat generation

RQ is the respiratory quotient

Converting O<sub>2</sub>STP to the volume of O<sub>2</sub> at the animal's core temperature, the general equation (V<sub>1</sub> \* P<sub>1</sub> / T<sub>1</sub>) = (V<sub>2</sub> \* P<sub>2</sub> / T<sub>2</sub>) is rearranged to solve for volume of oxygen consumed and the ideal gas law is used:

20 n = PV/RT (Ideal gas law: number of moles from pressure, volume, temperature)

VO<sub>2</sub>CON = (O<sub>2</sub>STP \* RefPO<sub>2</sub> / 273.15) \* ((T<sub>lung</sub> + 273.15) / PO<sub>2</sub>)

25 where,

O<sub>2</sub>MOLC = O<sub>2</sub> consumed / second = PO<sub>2</sub> \* VO<sub>2</sub>CON / (RGC \* (T<sub>lung</sub> + 273.15))

T<sub>lung</sub> = the temperature in the lungs obtained from a solution for the average temperature from the core to the skin obtained from integration.

30 MOLES/s O<sub>2</sub>, N<sub>2</sub>, & dry air AT 1: (1 refers to entrance of respiratory system,

while 2 refers to the exit, see **FIG 4**) (Air flow =  $f(O_2$  consumption)

$$O_2MOL1 = O_2MOLC / (EXTREF / 100)$$

$$N_2MOL1 = O_2MOL1 * (PCTN_2 / PCTO_2)$$

Demand for air =  $f(\%O_2$  in the air and elevation)

5

Note that as long as all 3 percentages add to 100%, no change in air flow occurs, unless one corrects for change in  $\%O_2$  in the air and elevation changes relative to sea level.

$$10 \quad AIRML1 = O_2MOL1 * ((PCTN_2 + PCTO_2 + PCTCO_2) / PCTO_2) * (RpctO_2 / PctO_2) *$$

$$(RefPO_2 / PO_2)$$

Air volume at STP (liters/s) \* (s/hour)

$$AirVol = (Airm1 * RGC * 273.15 / 101325.) * 3600.$$

15 Computing the vapor pressure at saturation for the subsequent calculation of actual

moles of water based on actual relative humidity,

$$rhsat = 100$$

20 CALL WETair(Tair, WB, rhsat, dP, BarPrs, E, ESAT, VD,  
RW, TVIR, TVINC, dENAIR, CP, WTRPOT)

Moles water/s in at 1 (entrance, see **FIG. 4**) based on relative humidity. Note that

humidity is set to 99% in Main if animal is in burrow for the current hour.

$$25 \quad WMOL1 = AIRML1 * (ESAT * (RELHUM / 100.)) / (BarPrs - ESAT * (RELHUM / 100))$$

MOLES/s of dry air AT 2: (EXIT)

$$O_2MOL2 = O_2MOL1 - O_2MOLC$$

$$N_2MOL2 = N_2MOL1$$

$$CO_2MOL = RQ * O_2MOLC$$

30

Total moles of air at 2 (exit, see **FIG. 4**) will be approximately the same as at 1

(entrance), since the moles of O<sub>2</sub> removed = approx. the number of moles of CO<sub>2</sub> added.  
Avogadro's number specifies the number of molecules/mole.

5                   AIRML2 = O<sub>2</sub>MOL<sub>2</sub> + CO<sub>2</sub>MOL \* ((PCTN<sub>2</sub> + PCTO<sub>2</sub>) / PCTO<sub>2</sub>) \* (RpctO<sub>2</sub> /  
PctO<sub>2</sub>) \* (RefPO<sub>2</sub> / PO<sub>2</sub>)

Setting up call to WETair; TEMP. OF EXHALED AIR close to AIR TEMP, assuming  
saturated air at exhalation,

10                  RELXIT = 100

Kangaroo physiology (Schmidt-Nielsen, K., *et al.* 1970. *Counter-current heat  
exchange in the respiratory passages: Effect on water and heat balance.* Resp. Physiol. 9:  
263-276) shows Ta,exit - Ta = 3C.

15                  TAEXIT = Tair + DELTAR

Not letting internal air go below 0 C for stability purposes:

20                  If (Taexit .lt. 1.0) then

                        Taexit = 1.0

                        Endif

Calculating saturation vapor pressure (Esat) at exit temperature.

25                  CALL WETair (TAEXIT,WB,repELXIT,dP,BarPrs,E,  
                        ESAT,VD,repW,TVIR,TVINC,dENAIR,CP,WTRPOT)  
                        WMOL2 = AIRML2\*(ESAT/(BarPrs-ESAT))  
                        ENTHALPY = U2-U1, internal energy only, *i.e.*, LAT. HEAT OF VAP are  
30                  only involved, since P,V, and T are assumed to be constant, thus not  
                        significant.

FLOW ENERGY, PV. (H = U + PV)

Moles/s lost by breathing: EVPMOL = WMOL2-WMOL1

5 Grams/s lost by breathing = moles lost \* gram molecular weight of water:

$$Mw,evap,resp = EVPMOL * 18.$$

A cap is put on water loss for small animals in very cold conditions by assuming they  
10 will seek more moderate conditions if they exceed this cap. This will improve stability for the  
solution method (based on data from W.R. Welch. 1980. *Evaporative Water Loss from  
Endotherms in Thermally and Hygrically Complex Environments: An Empirical Approach for  
Interspecific Comparisons*. J. Comp. Physiol. 139: 135-143). The maximum value recorded  
15 for Prairie Dogs was  $0.6 \text{ g/(kg-h)} = 1.667 \times 10^{**-4} \text{ g / (kg-s)}$ . The highest recorded rate was  
for a resting deer mouse at  $8 \text{ g/kg-h} = 2.22E-03^*$  (Edwards & Haines.1978. J. Comp. Physiol.  
128: 177-184 in Welch, 1980). For a 0.01 kg animal, the max. rate would be  $1.67 \times 10^{**-6}$   
g/s.

$$Tesval = 2.22E-03 * timbas * gmass / 1000$$

20  
If (gevap .gt. Tesval) then,  
gevap = Tesval  
endif

25 Kg/s lost by breathing:

$$gperhr = gevap * 3600$$

$$KGEVAP = GEVAP / 1000$$

Latent heat of vaporization from sub. DRYAIR (J/kg)

30

$$HTOVPR = 2.5012E+06 - 2.3787E+03 * Tlung$$

Heat loss by breathing (J/s) = (J/kg) \* (kg/s)

$$Q_{\text{resp}} = HTOVPR * KGEVAP$$

5

**b.) The skin subroutine.**

The equations used to solve for the mass of water lost by evaporation from skin (Wevap,skin), is

$$Wevap,skin = A_{\text{eff}} * h_D * (VD_S - VD_A)$$

10 Where  $A_{\text{eff}}$  is the effective surface area that behaves as a free water surface  $h_D$  is the mass transfer coefficient computed from the heat transfer coefficient,  $h_C$ , using the Colborn Analogy (Bird, R.B., Stewart, W.E., and E.N. Lightfoot. 1960. Transport Phenomena. Wiley and Sons, New York)

VD<sub>S</sub> is the water vapor density at saturation at skin temperature

VD<sub>A</sub> is the water vapor density at saturation at air temperature outside the animal's boundary layer.

The grams of free water absorbed from food (Mw,f) per hour, equals the total wet weight absorbed per hour minus the dry weight absorbed per hour, as in:

$$Mw,f = (GTOTHR - PCTDRY * GTOTHR) / PCTDRY$$

15  
16  
17  
18  
19  
20  
21  
22  
23  
24  
25  
26  
27  
28  
29  
30

The grams of metabolic water (Mw,i) formed per hour is,

$$Mw,i = GPROTH * 0.40 + GFATH * 1.07 + GCARBH * 0.56$$

The grams of water lost in urine produced (Mw,u) per hour is,

$$GUREA = GPROTH * 0.343$$

$$GURINE = GUREA / PTUREA$$

$$Mw,u = (GURINE - GUREA) / 1.0474$$

The water in feces (Mw,d), is

$$g \text{ wet weight absorbed/hr} = \text{DigEff} * g \text{ processed/hr}$$

$$g_{\text{proch}} = (GFREWA + GTOTHR) / \text{DigEff}$$

$$\text{WETFEC} = \text{gproch} - (\text{GFREWA} + \text{GTOTHR})$$

$$\text{Mw,d} = \text{WETFEC} * \text{PFEWAT}$$

5 The total amount of discretionary water available ( $\text{Mw,avail}$ ) per hour from gut and excretory system is calculated as a function of diet,

$$\text{Mw,avail} = \text{Mw,f} + \text{Mw,i} - \text{Mw,u} - \text{Mw,d}$$

Total discretionary mass from water is then,

10

$$\text{Mw,discr} = \text{Mw,avail} - \text{Mw,evap,resp} - \text{Mw,evap,skin}$$

### 3. Solving for the total amount of discretionary energy (Qdiscr).

15 The total amount of discretionary energy available to the animal ( $\text{Qdiscr}$ ) is then calculated as follows:

$$\text{Qdiscr} = \text{Qavail} - \text{Qgen}$$

#### iii. Calculating total activity time

20 The total annual activity time of the animal is a key variable linking the individual energetics of an animal (as calculated by the animal model **500** described below) to population and community level phenomena (some of which may be included in the calculation of other variables **800** step described below). For example, total activity time can be used to calculate certain life history variables like survivorship, growth and reproductive potential (because feeding frequency and handling time affect mass and energy intake by an 25 animal, and thereby discretionary mass and energy), that are, in turn, used to calculate population dynamics.

30 The temperature dependent activity/feeding frequency of an animal (*i.e.* the time during which an animal is active) is calculated as a linear function of the percentage of thermally available habitat (from the microclimate conditions output **400**). A summation of a day's preferred activity times over a month and over the year then yields total annual activity time for the animal.

The total annual activity time of the animal is a key variable linking the individual energetics of an animal (as calculated by the animal model **500** described below) to population and community level phenomena (some of which may be included in the calculation of other variables **800** step described below). For example, total activity time can  
5 be used to calculate certain life history variables like survivorship, growth and reproductive potential (because feeding frequency and handling time affect mass and energy intake by an animal, and thereby discretionary mass and energy), that are, in turn, used to calculate population dynamics.

The total annual activity time of the animal is calculated by summing the temperature-  
10 dependent activity/feeding frequency of the animal over all time intervals (over days, over months) totaling a year. The temperature-dependent activity/feeding frequency of the animal is determined by tracking the amount of time the animal is in its null condition as the animal model **500** is run – the null condition being initially defined by the user to be the normal activity/feeding time of the animal [*e.g.* whether the animal is active during the day (diurnal),  
15 night (nocturnal), dusk and dawn (crepuscular), etc.].

#### iv. Animal model conditions output **600**

The animal conditions output **600** may include many different types of calculations based on the user's preference. In general, the output **600** will include the values for several metabolic variables, the temperature-dependent activity/feeding frequency of the animal and the total annual activity time of the animal.  
20

The metabolic variables include the solutions generated using the animal model **500** for several energy and mass metabolic variables (see **FIG. 2**). The heat balance solutions yield values for the metabolic heat generation needed to maintain the animal's core temperature (Qgen), the amount of heat entering the animal (Qin), the amount of heat leaving  
25 the animal (Qout). The mass balance equations yield values for the discretionary mass from food and water (Mdiscr) by calculating the mass of food and water absorbed by the animal (Mf,a, Mw,a), the mass of food and water ingested by the animal (Mf,i, Mw,i), the mass of food and water excreted and evaporated (Mf,d, Mw,u, Mw,evap), and the mass of food and water metabolized by the animal (Mf,met, Mw,met). Also included among the metabolic  
30 variables calculated is the lung air flow (including total air mass and CO<sub>2</sub> production).

Optimal body size and other variables can be calculated for any given locality by

simply looping through the range of body sizes specified by the user and selecting the size that best meets user criteria, such as maximum discretionary energy (see System and Method of Implementation section below).

**d. Animal model conditions database 700**

5 The animal model conditions database **700** accumulates the animal conditions output **600** over all time intervals, localities and species for which the models are run. The cumulative data are organized in the database **700** in such a way as to facilitate further calculations and/or display options. The location and time information continues to be associated with the animal conditions **600** as calculated by the animal model **500**. This allows 10 for the subsequent coupling of the animal conditions data set **600** with its associated temporal and GIS based information on climate, topography and vegetation. In this way, they can be used to generate spatially and temporally explicit interpretations of animal energetics and behavior, and displayed **900** or made available for further calculations **800** as described below.

**e. Calculation of other variables 800**

15 Further calculations may be performed using information in the animal model conditions database **700**. When the animal model conditions data **700** are coupled with GIS based information on climate, topography and vegetation, they can be used to generate spatially explicit interpretations of animal energetics and behavior.

20 For example optimal body size that maximizes discretionary mass or energy or other variables, optimal behaviors, intake of pollutants (*e.g.* pesticides), growth and reproduction potential as function of discretionary mass and energy survivorship/mortality as function of total annual activity time, and spatial variation in all variables (*see* for examples of these kinds of calculations, Adolph and Porter 1993, 1996, refs. above; Porter 2000, ref. above). 25 The animal conditions data **700** may also be used to calculate community structure (if run over several species/body sizes).

The analysis of spatial variations is also possible using the present invention. An example is given in the description of the system and method of implementation section below.

**f. Display of results 900**

30 The data in the animal model conditions database **700** and generated by any further

calculations 800 performed, may be organized and displayed in any number of ways. Any number of kinds of tables and graphs may be generated to display the data to best communicate the results of the model. In particular, the data may be organized in tables particularly suited to use by spatial plotting software (such as ARCVIEW) to allow the data to be plotted in geographic space.

5 **g. Applications of the method.**

The method of the present invention can be applied to many and varied situations. Several examples follow.

10 **ii. Management and preservation of threatened or endangered species.**

One of the primary utilities of the present invention is to provide fully integrated microclimate and animal models which may be used in coordination to accurately predict the effects of climate and other environmental conditions on animals, that require relatively few, easily measured data to estimate food and water requirements, potential for activity time, growth, and reproduction for a wide variety of habitats. The fact that relatively few data are required is important to the present invention's application to animals in nature generally, because it eliminates the need for extensive sampling or smaller or otherwise difficult to sample populations. The present invention can generate the information necessary to identify potential reserves or transplantation sites, and to modify or manage existing habitats to optimize the growth, reproduction and survivorship of threatened or endangered species.

15 Today, many species of animals are endangered. Often the cause of the endangerment is loss of their natural habitats to development or other land uses. Efforts to conserve the species require knowledge of the animal's adaptations to the environments in which they evolved, including their basic energetics. The question becomes one of how the animal will react both physiologically and behaviorally to the changes in their environments due to the 20 changes in their natural habitats, displacement to new habitats, or other environmental influences.

25 In this example, the integrated microclimate and animal models of the present invention were used to calculate the metabolic costs and food requirements of an endangered species of parrot, the Orange-bellied Parrot of Tasmania and Australia (*Neophema chrysogaster*, see, Porter et.al, 2000. Amer. Zoo., 40:597-630). With only approximately 200 individuals still alive, reliable estimates of the metabolic cost, the necessary foraging time and

amount of food required to sustain the parrot in its seasonal habitats could lead to quantitative estimates of the amount of habitat needed to assure its survival. That information can then be used to guide conservation efforts to preserve or otherwise modify the environment of the parrot so that its discretionary energy and water, and activity time are optimized resulting in 5 increased growth, reproduction and survivorship.

Using the method of the present invention, parrot metabolism was calculated across a range of temperatures experienced by the bird. These calculations were then used to estimate the parrot's energy use requirements in its native habitat. The results for metabolic rate variation with changes in air temperature and with size of the bird (mass) are plotted in **FIG.**

10 **6.** These results suggest that temperatures lower than 5 degrees C are stressful to hatchlings of lower mass. The method was also applied to calculate the effects of a range of foodstuffs ingested by the birds, on their growth and reproduction. These resulting data can be used to guide conservation efforts of the birds.

**ii. How vegetation alters the effect of climate on food requirements,  
geographic range, and predator-prey interactions.**

Vegetation can have an effect on the microclimates experienced by animals in addition to its role as a food source for some. Several of these effects are reported in Porter et al. (2001. *Physiology on a landscape scale: plant-animal interactions*. Unpublished manuscript). Below are summarized the reported effects of climate on food requirements and geographic range. Knowing these effects, managers of animals may modify environments accordingly to ensure the well-being of the animals.

15 The present invention was employed to answer the question of how fires in Yellowstone National Park altered the nighttime thermal environment and energetic requirements of Elk overwintering in the park. Because the fires removed tree needles, the Elk were exposed to potentially cold stressful thermal conditions over the winter nights. The method of the present invention was employed to simulate the microclimates at the park in 20 burned versus unburned locations, and the energetic costs and food requirements of similar sized elk compared. The results indicated that Elk in unburned locations required 20-25% less diurnal energy than did Elk in burned locations. The results further indicated that the 25 differences in infrared radiation, not wind, resulting from the burn, was the major factor influencing the difference in energy requirements of the elk. Knowing these results, those

tending the Elk herds may be able to design feeding or other strategies to reduce the energetic stresses to the Elk, or otherwise modify their management practices.

The way in which the thermal environment and vegetation (representing available resources) interact to determine the distribution of an animal, was investigated using the 5 method of the present invention applied to the chuckwalla, *Sauromalus obesus*, in the southwestern desert of the US and Mexico. The models of the present invention were used to calculate temperatures in the chuckwalla's environments across the entire North American continent. Calculated patterns of degree days, coupled with GIS data on soil and vegetation types were compared to the known geographic distribution of chuckwallas. Plotting the 10 results and comparing among the effects of temperature and vegetation/food, conclusions could be made on which factor(s) limit the animal's distribution. It was discovered that the northern limit of distributions may be constrained by egg incubation requirements and that the other boundaries of the distribution may be constrained by vegetation/food requirements.

A plot of the degrees days available across the continent is shown in FIG. 7, with the 15 chuckwalla's range noted and the minimum degree days required for successful hatch of eggs specified (1705 degree days), by way of example. The plot represents the result of microclimate effects on soil temperature calculations for every degree latitude and longitude in North and Central America. Soil temperatures were calculated by the microclimate model of the present invention at the surface, and various depths below the surface. Only soil 20 temperatures at a 15 cm depth were accumulated into a measure of "degree days." The calculations were for horizontal exposed soil with no shade on it. Successful chuckwalla egg incubation requires approximately 1700 degree days. Almost all of the current chuckwalla distribution lies in areas where the soil temperatures meet these minimum incubation requirements. If soil temperature alone is considered, the resulting plot suggests that the 25 species should be able to live in Mexico and Central America. Why not? The other analyses suggest that vegetation type may be a critical variable limiting the chuckwallas distribution to the east, west and south. These results show the present invention may be employed to help manage the chuckwalla population in order to, for example, enable it to expand to the south, east or west, by modifying the vegetation/food available to it in those areas.

30 **iii. Other examples of applications of the present invention.**

Many other uses of the present invention are possible. Above are represented a few of

the uses relating to the conservation and management of animals. Those examples may be expanded to include applications to the management of biodiversity, zoo populations and the like.

Other uses may include the analysis of disease vectors (e.g. mosquito vector) and how the effects of climate on their distributions may affect the spread of diseases. Still other uses include how pesticides may effect the energetics and survivorship of animals by quantifying the exposure of the animals; how the microclimate conditions experienced by animals stored in the cargo holds of airplanes are affected by the conditions they experience in order to increase survivorship by better controlling those environments (for example, carbon dioxide production by animals and oxygen availability as a function of the type of cargo hold, air flow and altitude); calculation of activity time, mass, and energy budgets for rare and endangered species to aid in their management (examples of species already investigated using the present invention include the giant panda of China, the Arabian Oryx on the Arabian Peninsula, the Yunnan snub nosed monkey on the China-Burma border, Puerto Rican parrots in Puerto Rico, marsupial gliders in Australia); assessment of the impact of manmade disturbances on the time, energy, and mass balances of rare and endangered species; forensic analyses to assess approximate time of killing of rare and endangered species in a natural habitat; environmental impacts of controlled burns in forests or national parks; assessment of climate change on distributions of animals in the past, present, or future; assessment of the impact of climate change on animal body size in the past present or the future; identification of regions of high natural selection pressures on animals in space and time; the design of animal shelters and animal husbandry practices in developing countries; and, dynamic changes in food web structure as influenced by climate, topography, and vegetation. This is a partial list of present and potential applications of the present invention.

25

#### **DETAILED DESCRIPTION – METHOD & SYSTEM OF IMPLEMENTATION**

As described above, the method for calculating the effects of environmental conditions on animals of the present invention includes the provision of databases of environmental conditions **100** and animal characteristics data **190** for use in forming sets of environmental conditions **120** and animal **170** data to be input to the microclimate **300** and animal **500** models. These databases (**100** and **190**) may be very large (currently on the order of 9 terabytes/table for the

database MySQL). If used as input files instead of database tables, their size limits their accessibility by users who do not have access to larger mainframe computers. Such users are limited by the amount of memory and speed of their computers. The present invention using Practical Extraction and Report Language (PERL) and MySQL, addresses this problem by 5 providing a method and system for its implementation on smaller computers, including personal computers. This allows many more users access to the methodology of the present invention and should enable its more widespread use among researchers, conservationists and other parties interested in understanding and managing animals.

Referring to **FIGS. 8 and 10**, one embodiment of the system and method for 10 implementing the present invention is summarized in a flow chart (**FIG. 8**) and basic system drawing (**FIG. 9**). **FIG. 8** is presented to explain the basic steps in the method of implementation of the present invention that allow a user to access and process the large amounts of data necessary, using minimal RAM memory and disc space on a computer. Multiple modes of implementation of the present invention are, of course, possible. As 15 depicted in **FIGS. 8 and 10**, the system is a client-server system, where the user's computer **3000** is on the client side and the server **3010** may be located elsewhere on an Intranet or Internet. The same basic methodology could, however, be employed on a single computer with sufficient memory and disc space to store the databases and run the programs.

The method comprises the generation of a graphical user interface (GUI) to the Web 20 browser **3020** of the user's computer **3000** (**1000** and **1010** in **FIG. 8**). The GUI can be customized to suit the particular application. For example, it can be customized for use by managers of endangered species to provide them choices and options that users in that field might typically want, or for use by environmental consultants. Likewise, an alternative GUI 25 may be customized with features more appropriate to the researcher in a lab or field setting, or the like.

In this embodiment, the GUI is provided in Hypertext Markup Language (HTML) for 30 implementation with the client's Web browser **3020** and is generated by a PERL program running at the server. However other types of Common Gateway Interface (CGI) programming languages may be employed besides PERL, and the GUI provided in other languages besides HTML. The PERL driver, however, enables use of the databases rather than files for the inputs/outputs, thereby minimizing the memory required and speeding the

processing. This, in turn, allows for the implementation on smaller computers. It also allows the use of massive sets of data, thereby enabling the spatial and high resolution temporal analyses possible using the present invention.

The user then inputs a set of variables and/or conditions **150** to be used by the

5 microclimate **300** and/or animal **500** models of the present invention **1020**. A PERL program at the server (**3030**, representing all computer programs running at the server including the animal and microclimate model programs, output display programs, and the like) receives the user input **150** in HTML, or by direct manipulation of the PERL code **1030**. The PERL program also reads one or more database tables contained in the environmental conditions 10 database **100** and that supply input information about the environmental conditions (e.g., elevation, slope, aspect, vegetation type, and substrate type as a function of geographic coordinates) by locality **1040**. After processing each locality input data set, the PERL program modifies the input data file to the microclimate model **1050**. After each input file modification, the PERL program calls the microclimate program **300** to run **1060**. Two output files (called metout and soil) are created that form the above ground and below ground microclimate conditions **400** used as input for the animal model **500**. As depicted in **FIG. 8**, the microclimate model **300** is programmed in FORTRAN, however, other programming languages may alternatively be employed.

20 Depending upon how the user has specified animal data input (in the user-defined variables and conditions **150**), the PERL program will modify the animal input database **190** to form the set of animal characteristics data **170** for input to the animal model program **500**. The animal model program **500** is then run using the microclimate conditions **400** output from the microclimate model **300**, and the animal characteristics data set **170, 1070**. The animal conditions output **600** is stored in an animal conditions database **700, 1080**, for later display 25 **900** and/or further calculations **800**.

If more time intervals remain, the animal model is run again **1070**. At the end of all time interval runs, the program checks if the user has specified that other animal species are to be considered. If so, the program repeats from step **1040** until all species are considered. The program then likewise executes over all localities under consideration, by repeating step **1040** 30 on.

At the end of all runs, the data in the animal conditions database 700 may be accessed for further calculations 800 or for display 900. In FIG. 8, an example of displaying the results geographically is portrayed at 1090, in which the data are plot in GIS format using Arcview. These data are then provided to the GUI at the user/client 2000, and the plot, or 5 other results, displayed.

The user may specify that any number of calculations be made by the model at 1020. Depending on those specifications, the model(s) may repeat in several iterations, varying the data inputs each time. In this way a user may compare outputs for different body sizes or other animal variables to find, for example, an optimal body size or how variables vary 10 spatially (described below), among many other possibilities.

*Optimal body size.* Optimal body size and other variables can be calculated for any given locality by simply looping through the range of body sizes specified by the user and selecting the size that best meets user criteria, such as maximum discretionary energy. These kinds of loops are in the driver code in PERL and are external to the FORTRAN executable elements called by the PERL code.

*Spatial analysis of animal energetics.* The spatial analysis of animal energetics starts by assembling data files that include digital elevation maps (DEMs). This process can often be done by accessing files of quadrangle maps from various sources online such as various United States government agencies. Alternatively, private corporations either have available or will create for a fee, digital elevation maps of anywhere on earth, thus enabling the input of geographic data for just about anywhere to the models of the present invention. Digital elevation maps can be displayed in GIS programs, such as ArcView. Boundary maps or other geographic information can be superimposed on these images. ArcView can then translate this topographic image into an analysis of elevation. Slope and aspect (azimuth) of each 20 "pixel" of information can be calculated as well. These maps have a resolution of 30 m, so each "pixel" is 30 m on a side. These data can be exported into a text table. The collection of these data from separate tables into a single table that can be read by PERL (or other similar program) is easily automated.

Each row of a table represents a unique location and the data associated with that 25 location. For example, a row of data may contain latitude, longitude, elevation, slope, aspect, vegetation type, and soil type. Those data are then loaded into a database table. The PERL

program reads the input database table, one row at a time. Those data are used to modify the input data file for the microclimate model **300**, basically modifying the geographic coordinates and other appropriate data in the input file to correspond to the particular location represented by the current row being read from the database table. Generally, a full year of 5 microclimate simulations are run for each location and then the output is passed to the animal model **500**.

After all animal simulations are done for the same location, the PERL program reads another line from the database input table and repeats the process. After all calculations for a location are completed, the animal conditions output data **600** are written to the animal 10 conditions database **700** output table. Its format is similar to the input data table, in that the first two entries in every row are the latitude and longitude followed by various animal output data for each month of the year and accumulated over the entire year. This output data table becomes the input table for ArcView or other GIS program that can plot discrete columns of output as a function of latitude and longitude and display the information graphically. **FIG. 9** 15 is an example of such a plot showing the amount of discretionary energy (kJ/d) of a 60 kg Mountain Lion for the month of July, as a function of slope and aspect of the topography for a particular quadrangle of its range. Activity time, as well as other variables, may likewise be plotted spatially.

20 While the above description contains many specificities, these should not be construed as limitations on the scope of the invention, but rather as an exemplification of the presently preferred embodiments thereof. The above-described embodiments are set forth by way of example and are not for the purpose of limiting the present invention. It will be readily 25 apparent to those skilled in the art that obvious modifications, derivations and variations can be made to the embodiments without departing from the scope of the invention. Accordingly, the scope of the invention should be determined not by the examples given, but by the appended claims and their legal equivalents.
